To fashion a flint implement both knowledge of the tricks of the trade and skill in execution are required. Watching the flint knappers at Brandon can teach the student many a 'wrinkle', but any attempt to do likewise soon demonstrates the overriding importance of long and patient practice. The Pitt Rivers Museum authorities at Oxford have recently issued their first Occasional Paper on Technology, and it is entitled "The Manufacture of a Flint Arrowhead by Quartzite Hammer-stone"*. The author is Sir Francis Knowles and the work is plentifully illustrated. One can only regret that the writer had not the chance to collaborate in a more extensive work with M. Contier who, though he has, so far as I know, published nothing, is perhaps the most skilful maker of flint tools in existence.

M. Contier is, or was, an ornamental stonemason with a workshop in the outskirts of Paris; but he was also a pupil of Breuil in the typology of flint implements, and the combination has been very fruitful. It was he who showed that the single-faceted, highly inclined striking platform of the so-called Clacton technique involved the swinging of a nucleus against a stone anvil; while the right-angled platform of the Levallois implements could be produced by vertical blows on the nucleus with a hammer-stone. Again, it was Contier who discovered the possibilities of the 'wood technique': the striking of the core, held in the hand, with a baton of wood instead of with a hammer-stone, whereby flaking similar to that long recognized as characteristic of Acheulean tools can be produced. Actually, the use of the softer hammer partially resolves the phenomenon of percussion produced by a stone hammer into that of pressure. A dictum of Contier's used to run—the Chellean technique is that of the anvil, but Acheulean man held the flint core in his hand and hit it with a wooden baton. He also, like Dr. Leakey, had definite views as to how the various types of burins were made.

But Contier was essentially a craftsman. Sir Francis Knowles, though with a limited, definite objective, has given us the written word upon this subject of technique. He is concerned only with the manufacture of arrowheads, using a quartzite hammer-stone, not an iron hammer as do the knappers of Brandon. His paper is the book of words for doing this. He tells us how to choose the materials, how to hold and hit them, how to 'turn the edge' of the flake, etc. His instructions are indeed what a cook would call the 'recepe' for the production of a complicated and beautiful piece of craftsmanship. Very definitely papers of this kind have value; still far too little is known about the material flint and the various ways in which it can be fractured. Incidentally, anyone who has tried his hand at it will know the difficulty of describing in words

* Pitt Rivers Museum, University of Oxford. Occasional Papers on Technology, 1: The Manufacture of a Flint Arrow-head by Quartzite Hammer-stone. By Sir Francis Knowles. Pp. 38+6 plates. 5s.

knapping techniques and processes, and Sir Francis is to be congratulated that in the work under notice the reader, with only a very little concentration, will readily appreciate the way the author sets to work to make his specimens. M. C. BURKITT.

## GEOPHYSICS AND GEOMORPHOLOGY IN U.S.S.R.

THREE numbers of the *Bulletin de l'Académie des Sciences de l'URSS*, Série Géographique et Géophysique (Nos. 4–5, 1941; No. 2, 1943; No. 3, 1943), which have recently reached us, give some idea of the progress made in geophysics and geomorphology in U.S.S.R. For convenience the papers are grouped under four headings: (1) Atmosphere, (2) Hydrosphere, (3) Lithosphere, and (4) Climatology.

(1) *Atmosphere.* A. M. Obuhov (453; 1941) presents a mathematical study of the energy distribution in the spectrum of a turbulent flow; M. E. Schwez, in his first paper (467; 1941), gives a mathematical study of the vertical velocities in a moving air mass, and in the second paper (No. 2, 55; 1943), a mathematical study of the velocity of wind and the turbulent diffusion; S. L. Ponisovski (432; 1941) discusses the state of the *E*-layer of the ionosphere at twilight; A. J. Driving, A. V. Mironov, V. M. Morozov and I. A. Khvostikov, in their study of the polarization and absorption of light in natural fogs (No. 2, 70; 1943), have found a discrepancy between observation and theory which they propose to solve by postulating the presence of submicroscopical droplets.

(2) *Hydrosphere.* Mathematical treatment of turbulence is attempted by M. Millionshchikov (433; 1941), who discusses the turbulent heat conduction of sea water; by W. Stockmann (483; 1941), who discusses the horizontal components of velocity of sea currents; and by K. V. Shutilov (447; 1941). L. S. Leibenson (411; 1941) presents a mathematical treatment of the movements of gas-containing liquid in a porous medium.

(3) *Lithosphere.* Magnetic anomalies in the Moscow region are discussed by A. G. Kalashnikov (No. 2, 83; 1943), thermal anomalies in the earth's crust caused by strata and rock masses of different thermal conductivities are discussed by N. N. Korytnikova (No. 3, 115; 1943); a new method of measurement of temperature in salt mines is proposed by S. A. Kraskovsky (No. 3, 134; 1943); a mathematical study of the processes of freezing and thawing is given by S. S. Kovner (No. 3, 143; 1943); and V. V. Beloussov (No. 3, 147; 1943) outlines a new hypothesis of the development of the earth's crust as due to the migration of radioactive elements. J. A. Skvorzov (Nos. 4–5, 501; 1941) discusses the methods of geomorphological analysis and mapping; and V. V. Galitzky (No. 2, 89; 1943) gives an account of the geomorphology of the Kara-Tau region (north-west Tian-Shan).

(4) *Climatology.* The problem of the gradual rise of the temperature of the arctic regions is discussed by B. L. Dserdsejevsky (No. 2, 60; 1943) and the effectiveness of synoptical weather predictions is discussed by M. A. Omshansky (No. 3, 161; 1943).

All papers are provided with summaries, either in English or German, but some of these summaries are too brief to be of much value. S. I. TOMKEIEFF.

## FORTHCOMING EVENTS

*(Meeting marked with an asterisk * is open to the public)*

### Tuesday, November 14

SOCIETY OF CHEMICAL INDUSTRY (joint meeting of the CHEMICAL ENGINEERING GROUP, the AGRICULTURE GROUP, and the INSTITUTION OF CHEMICAL ENGINEERS) (at the Institution of Mechanical Engineers, Storey's Gate, St. James's Park, London, S.W.1), at 2 p.m.—Conference on "Grass Drying" (Dr. S. J. Watson: "Grass Drying—Chemical Aspects"; Mr. A. Goldberg and Mr. A. C. Bartelli: "Grass Drying—Engineering Aspects"; Mr. D. Fairclough: "Grass Drying—The Farmer's Viewpoint").

CHADWICK LECTURE (at the Royal Sanitary Institute, 90 Buckingham Palace Road, London, S.W.1), at 2.30 p.m.—Mr. Guy Howard Humphreys: 'Some Modern Trends in Sanitary Engineering" (Bossom Gift Lecture).*

ROYAL INSTITUTION (at 21 Albemarle Street, Piccadilly, London, W.1), at 5.15 p.m.—Mr. Christopher F. C. Hawkes: "Prehistoric Britain", (ii) "The Later Prehistoric Centuries".

ILLUMINATING ENGINEERING SOCIETY (at the E.L.M.A. Lighting Service Bureau, 2 Savoy Hill, Strand, London, W.C.2), at 5.30 p.m.—Mr. J. N. Aldington: "Bright Light Sources".

INSTITUTION OF CIVIL ENGINEERS (ROAD ENGINEERING DIVISION) (at Great George Street, Westminster, London, S.W.1), at 5.30 p.m.—Mr. A. H. D. Markwick: "The Basic Principles of Soil Compaction and their Application".

### Wednesday, November 15

ROYAL SOCIETY OF ARTS (at John Adam Street, Adelphi, London, W.C.2), at 1.45 p.m.—Dr. L. Hartshorn: "High-Frequency Heating".

INSTITUTE OF FUEL (at the Institution of Mechanical Engineers, Storey's Gate, St. James's Park, London, S.W.1), at 2.30 p.m.—Mr. B. F. Karthauser: 'The Development and Design of Shell Type Boilers".

BRITISH INSTITUTION OF RADIO ENGINEERS (NORTH-EASTERN SECTION) (at the Neville Hall, Westgate Road, Newcastle-upon-Tyne), at 6 p.m.—Mr. A. H. Hoult: "Theory of Rectification".

SOCIETY OF CHEMICAL INDUSTRY (FOOD GROUP) (joint meeting with the CARDIFF SECTION and the CARDIFF SECTION OF THE ROYAL INSTITUTE OF CHEMISTRY) (at the Newport Technical College, Clarence Place, Newport, Mon.), at 6.30 p.m.—Dr. E. B. Hughes: "Chemistry in the Kitchen".

SOCIETY OF CHEMICAL INDUSTRY (BIRMINGHAM SECTION) (joint meeting with the ROYAL INSTITUTE OF CHEMISTRY) (in the Chamber of Commerce, New Street, Birmingham), at 6.30 p.m.—Mr. C. W. Bonniksen: "Some Properties and Applications of Alginic Acids and Alginates".

### Thursday, November 16

CHEMICAL SOCIETY (at Burlington House, Piccadilly, London, W.1), at 2.30 p.m.—Mr. G. M. Phillips, Mr. J. S. Hunter and Mr. L. E. Sutton: "Investigation of the Occurrence of the Co-ordinate or Dative Link by Electric Dipole Moment Measurements"; Mrs. G. A. Gilbert, Mr. F. Smith and Mr. M. Stacey: "A Constitutional Synthesis of Cellobiose and Gentiobiose".

ROYAL INSTITUTION (at 21 Albemarle Street, Piccadilly, London, W.1), at 2.30 p.m.—Sir James Jeans, O.M., F.R.S.: "Old and New Descriptions of the Astronomical Universe", (iii) "Galaxies".

ROYAL SOCIETY OF ARTS (INDIA AND BURMA SECTION) (at John Adam Street, Adelphi, London, W.C.2), at 2.30 p.m.—Dr. R. Maclagan Gorrie: "The Place of Mechanized Equipment in Indian Soil Conservation".

LONDON MATHEMATICAL SOCIETY (at the Royal Astronomical Society, Burlington House, Piccadilly, London, W.1), at 3 p.m.—Prof. S. Mandelbrojt: "On the Regularization of Sequences".

ROYAL SOCIETY (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Sir Harold Hartley, F.R.S.: "Antoine Laurent Lavoisier" (Lavoisier Bicentenary Lecture).

CHEMICAL SOCIETY (in the Department of Chemistry, University College of North Wales, Bangor), at 5.30 p.m.—Prof. R. D. Haworth, F.R.S.: "Oxidation of Phenols".

BRITISH INSTITUTE OF RADIOLOGY (in the Reid-Knox Hall, 32 Welbeck Street, London, W.1), at 8 p.m.—Symposium on "Physical, Biochemical and Therapeutic Aspects of Volume Dose".

### Friday, November 17

SOCIETY OF CHEMICAL INDUSTRY (PLASTICS GROUP) (at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 2.30 p.m.—Discussion on "Polymer-Plasticiser Interaction" (to be opened by Dr. R. F. Tuckett and Miss E. M. Frith).

ROYAL INSTITUTION (at 21 Albemarle Street, Piccadilly, London, W.1), at 5 p.m.—Vice-Admiral Sir John A. Edgell, K.B.E., F.R.S.: "Ocean Passages, Depths and Currents—the Work of the Hydrographic Department in Peace and War".

INSTITUTION OF MECHANICAL ENGINEERS (at Storey's Gate, St. James's Park, London, S.W.1), at 5.30 p.m.—Dr. H. E. Wimperis: "Research and Development in Aeronautics" (Thirty-first Thomas Hawksley Lecture).

INSTITUTION OF ELECTRICAL ENGINEERS (MEASUREMENTS SECTION) (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Mr. G. E. Moore: "Planning the Future Electricity Meter".

NORTH-EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS (in the Lecture Theatre of the Mining Institute, Newcastle-upon-Tyne), at 6 p.m.—Mr. J. S. Thompson: "In Search of Efficiency".

CHEMICAL SOCIETY (in the Royal Technical College, Glasgow), at 7.15 p.m.—Mr. R. P. Bell, F.R.S.: "The Value of the Resonance Concept in Chemistry".

### Saturday, November 18

QUEKETT MICROSCOPICAL SOCIETY (at the Royal Society, Burlington House, Piccadilly, London, W.1), at 2.30 p.m.—Papers.

SHEFFIELD METALLURGICAL ASSOCIATION (at 198 West Street, Sheffield, 1), at 2.30 p.m.—Mr. R. A. Hacking: "Technical and Economic Problems in the Heavy Iron and Steel Industry".

## APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

LECTURER (full-time) in the Ashington Mining School (applicants should possess a Degree in Physics or General Science and be prepared to take MATHEMATICS to School Certificate standard)—The Director of Education, County Hall, Newcastle-upon-Tyne 1 (November 15).

GRADUATE LECTURER (full-time) IN MATHEMATICS in the Medway Technical College, Gillingham—The District Education Officer, Fort Pitt House, Rochester (November 16).

LECTURER (full-time) IN MECHANICAL ENGINEERING in the Schools of Technology, Art and Commerce, Oxford—The Chief Education Officer, City Education Office, 77 George Street, Oxford (November 17).

SPEECH THERAPIST (full-time) to undertake duties in the areas of the Bridgwater, Taunton and Yeovil Education Committees—The Clerk to the Taunton Borough Education Committee, Education Office, Municipal Buildings, Taunton (November 18).

AGRICULTURAL TRAINING OFFICER to organize the scheme for the training in Agriculture and Horticulture of men and women released from War service—The Chief Executive Officer, Herefordshire War Agricultural Executive Committee, 4 St. John Street, Hereford (November 20).

HEAD OF THE ENGINEERING DEPARTMENT—The Principal, Stockport College for Further Education, Stockport (November 20).

LECTURER IN BIOLOGY, with Botany or Physiology as subsidiary subject—The Clerk to the Governors, South-East Essex Technical College and School of Art, Longbridge Road, Dagenham (November 20).

LECTURER IN GEOGRAPHY—The Principal and Clerk to the Governing Body, Wigan and District Mining and Technical College, Wigan (November 22).

LECTURER (man or woman) IN MATHEMATICS—The Registrar, University College, Southampton (December 1).

ASSISTANT (temporary) IN THE DEPARTMENT OF ZOOLOGY—The Deputy Director, Museum and Art Gallery, Bristol 8 (December 9).

ENGINEERS by the Government of Nigeria for the Posts and Telegraphs Department—The Ministry of Labour and National Service, Room 432, Alexandra House, Kingsway, London, W.C.2 (quoting Reference No. D.971.A) (December 11).

DIRECTOR OF RESEARCH—The Secretary, British Internal Combustion Engine Research Association, 111–112 Buckingham Avenue, Slough, Bucks. (December 31).

LECTURER IN EXPERIMENTAL ZOOLOGY—The Registrar, The University, Liverpool (January 5).

DIRECTOR—The President, British Coal Utilisation Research Association, 13 Grosvenor Gardens, London, S.W.1 (January 31).

MASTER FOR ENGINEERING SUBJECTS, including Workshop Practice—The Principal, Erith Technical College, Belvedere, Kent.

TEACHER FOR PHYSICS AND CHEMISTRY—The Acting Principal, Technical Institute, Sheerness.

GRADUATE ASSISTANT (temporary) to teach chiefly PHYSICS and MATHEMATICS in the Thomas Richards Technical Institute, Tredegar—The Acting Director of Education, Higher Education Department, County Hall, Newport, Mon.

SPEECH THERAPIST—The Director of Education, Shire Hall, Nottingham.

BOTANIST (male) IN THE BRANCH OF PLANT PATHOLOGY AND BOTANY of the Department of Agriculture, Southern Rhodesia—The Official Secretary, Rhodesia House, 49 Strand, London, W.C.2.

# A COLLEGE OF AERONAUTICS

AN Interdepartmental Committee on the Establishment of a School of Aeronautical Science was set up in October 1943, under the chairmanship of Sir A. H. Roy Fedden, who had just returned from a mission to the United States, where he had studied, among other matters, the system of aeronautical education in that country. The members of the committee dealing with the scheme were Sir A. H. Roy Fedden (chairman); Sir Alan Barlow, Treasury; Commdr. M. S. Slattery, Admiralty; Mr. W. P. Hildred, Air Ministry; Air Marshal Sir Ralph Sorley, Ministry of Aircraft Production; Sir John Stephenson, Dominions Office; Dr. W. Abbott, Ministry of Education; Sir Charles Darwin, Department of Scientific and Industrial Research; Sir B. Melvill Jones, Aeronautical Research Committee; and Sir Walter Moberly, University Grants Committee. Detailed memoranda and oral evidence were given by representatives of the various interests concerned, a list of which is added to the report*.

The Committee's report states that the object of the suggested college should be to provide a high-grade engineering, technical and scientific training in aeronautics for selected students to fit them for leadership in the aircraft industry, civil aviation, the Services, and for education and research. Sir Stafford Cripps, Minister of Aircraft Production, has already stated, in the House of Commons, that the Government accepts the report in principle and that the Air Ministry is making temporary accommodation available. It is understood that this is to be at Abingdon Aerodrome, Oxfordshire. The cost of this adaptation is likely to be about £150,000, with an additional £300,000 for equipment. The complete scheme, which it is suggested should be situated at either Aldermaston in Berkshire or Dunsfold in Surrey, will cost £2,610,000, with an annual upkeep of £380,000. About £150,000 would also be needed for removing and adapting apparatus from the temporary to the permanent site, and this must be regarded as an expenditure justified by the urgency of the need for starting the scheme at once.

While the efficient use of any applied science by industry must depend upon a continuous flow of scientifically trained entrants, the aeronautical world makes an even greater demand in that its new men need a more comprehensive training. They must be scientific men first, probably either physicists or engineers, and then be further trained in the technology of the application of their science to aeronautics. This is particularly true of engineering, where many problems arise that are peculiar to aircraft and aero-engine design and construction. Education has its own need as well. Facilities for obtaining the more elementary and technological training need to be much more widely spread over the country than they are at present. Such courses will be able to give the shorter theoretical and more practical training to those needing only this, in their own localities, and

* Ministry of Aircraft Production. A College of Aeronautics: Report of the Interdepartmental Committee on the Establishment of a School of Aeronautical Science. Pp. ii+98. (London: H.M. Stationery Office, 1944.) 2s. net.

will also provide a suitable flow of candidates to the proposed college, as well as to the universities. The Ministry of Education is already preparing plans for such courses in many of the local technical colleges and institutions, under extensions of the National Certificate scheme, and some of the universities are considering the question of undergraduate courses in aeronautics and aeronautical engineering.

Many of the Dominions, India, and the Colonies are moving in this matter, and it would serve a double purpose if they also encouraged their students to attend a central establishment in Britain for the completion of their training. All such schemes will form a reservoir from which the best men can be drawn to proceed to a higher education such as this college will provide.

The report also says: "We believe that progress will now depend less on the genius and resource of individuals and more on the organized investigation and experimentation of trained workers working in teams and using large-scale equipment. If so, then the College is essential to the future of the industry." This postulates a further outlook for such a scheme. It will train research workers and produce results of a kind that will be different from, and will not in any way trespass upon the province of, the accepted type of research establishment.

Another aspect that has never received sufficient attention in the past is the more scientific aspect of flight and flying operations. Such problems have come within the province of the Fighting Forces up to the present, and have presumably been investigated by them within their own organizations. The coming of long-distance transport, with its possibilities of stratosphere operation, bring problems for the physicist, engineer, flying operator and the pilot that can only be properly solved by teams of workers, some of whom are pilots trained in the more scientific aspects of flight, working in an atmosphere of experimentation such as would be found in a college of the kind proposed.

The principal function of this college will be to provide a two-year advanced training in aeronautics for about fifty students. It is suggested that they should be of university graduate standard, with at least one year of works experience, although it is emphasized that the possession of a degree should not be considered to be essential.

Shorter courses of a more specialized nature, either to provide training for administrators who do not require complete technical knowledge, or as refreshers for men already engaged in the profession, are contemplated, up to the numbers of a further two hundred students.

The syllabus will contain five main subjects: aerodynamics; aircraft structures, engineering and design; aircraft equipment; engines and systems of propulsion; production, administration and maintenance. Flight and operations will be included, embracing full-scale experimental work and flight testing.

The teaching and experimental work will be in the hands of a professor with a suitable permanent staff in each of the five branches. Specialist subjects can best be dealt with in short courses by visiting lecturers, who are engaged on that work professionally, possibly with the assistance of some of the permanent staff from the point of view of the technique of teaching. The short courses will obviously be principally of this class of lecture, while the full two-year course will have more of the fundamental science type of teaching, with a judicious mixture of specialist work. It is hoped to combine some appropriate experience in flying and flight conditions with all the courses. The establishment will naturally be in the hands of a principal with the necessary administrative staff; advised by a governing body representing the aircraft industry, the universities, the Government and Service departments, the Dominions and the Royal Aeronautical Society.

The report suggests that the college should be placed under the Ministry of Education for administration purposes, which would be given a special vote for its expenditures. It is also hoped that a Royal Charter would be granted.

The equipment of such a school will be large and expensive, and will need careful thinking out if it is not to lose its usefulness through obsolescence in a comparatively short time. It will need to be chosen to illustrate basic principles rather than to compete in modernity with the latest equipment of a professional research establishment. For example, wind-tunnels, which would inevitably be the principal equipment of the aerodynamics section, always tend towards greater 'Reynolds' number', which is obtained by a combination of increases in size, wind-speed and internal pressure. All these inevitably add to the complication of the apparatus, the rate at which experiments can be carried out and the cost. It is more than likely that all these points would make a high Reynolds' number tunnel unsuitable for demonstrating the principles of aerodynamics to students. The measurement of a force by the simple counterpoising of it by a weight is so much more obvious than, say, balancing it by an electric solenoid where the reading merely becomes a figure on the dial of a measuring instrument. The report suggests a battery of smaller tunnels, and one of higher speed for the more advanced work appropriate to the college.

For aircraft design the equipment will be mostly testing machines and rigs for the investigation of strengths of structural components. It is recommended that one slow-speed general-purpose wind tunnel be provided here, of sufficient size to accommodate full-size aircraft parts. The provision of this will avoid interference with the programme of work in the aerodynamics section. Aircraft equipment will probably need a multitude of small items appropriate to the testing and development of instruments, electrical, and electronic work in general.

Engines and systems of propulsion will demand a good deal of equipment to cover the work. Reciprocating engines will need facilities for tests on both single-cylinder research units and complete engines up to the largest sizes. Gas turbines must also be investigated, although in the present state of knowledge of these it is difficult to foresee just what equipment may ultimately be necessary. Test rigs will be needed for problems in the development of super-charging,

carburation, ducting, propellers, accessories, and for tests on fuels and oils.

'Production and materials' will need typical workshops sufficiently equipped for students to fabricate such parts as they may be investigating, a standards room and an inspection department. The metallurgical outlook, both practical and theoretical, will need special equipment covering chemistry, metallography, crystallography and plastics.

'Flight and operations' will obviously call for an aerodrome with the usual facilities, and a fleet of aircraft of various types. Using aircraft as flying laboratories requires a very well-equipped maintenance workshop with the right type of personnel, and a comparatively large fleet of machines to ensure continuity of demonstration.

In putting forward this scheme, the aeronautical world has given a lead that might well be followed by many industries that make use of applied scientific and technical knowledge. It is becoming increasingly evident to-day that there is a distinct gap between the end of a scientific university type of training, and a correspondingly responsible position in the appropriate profession. Some postgraduate training is necessary, of an advanced technical nature, rather different from the specialized research which is the only work the universities offer at present to postgraduate students. It is obvious that such training can best be given in a school, properly equipped and staffed by teachers who are specialists both in education and the appropriate professional work. Such students need to take the telescopic rather than the microscopic view of their technology. It is not too much to hope that this school will prove to be the forerunner of many others in various industries.

It is a pity that no situation nearer the centre of London could have been found. The technology of aeronautics is so closely related to the various societies which are all established in the heart of London that a situation within say the orbit of 'London Transport' would have seemed almost a necessity. There are still one or two large R.A.F. aerodromes within this range that will surely be made redundant in peace-time by the increasing speed and range of modern service aircraft.

Probably the greatest difficulty that the Ministry of Education will meet in the administration of this college will be to find the necessary teaching staff. It must be realized, as is appreciated by all educationists, that there is something in the art of teaching, and that the man who may be an acknowledged expert on his subject is not necessarily the best to impart that knowledge to a class of students. The reservoir from which such men can be drawn at present must be extremely limited.

The Government has shown considerable courage in embarking upon this scheme at a time when the ending of the War must create a period of uncertainty in the aircraft industry. It is to be hoped that those who control the world of aircraft and aero-engine design and construction will find themselves able to take as long a vision, and provide employment for such students, with both duties and salary in keeping with the training that they have undertaken.

# PROGRESS OF PLANT VIRUS RESEARCH

## Plant Viruses and Virus Diseases

By F. C. Bawden. (A New Series of Plant Science Books, Vol. 13.) Second entirely revised edition. Pp. xiv+294. (Waltham, Mass.: Chronica Botanica Company; London: Wm. Dawson and Sons, Ltd., 1943.) 4.75 dollars.

It is just over half a century since the discovery of the first virus, that of tobacco mosaic, and it is perhaps fitting that during the last ten years it is the study of this virus which has yielded such fruitful results. There are, however, some outstanding questions which need to be answered concerning viruses and particularly plant viruses. First and foremost perhaps, as suggested by Mr. Bawden, there is the behaviour of viruses in their natural environment, the cells of the host. In other words, how do viruses multiply? This aspect may, as the author hopes, provide the next great advances in knowledge of the subject. Let us hope so too, but it is such a fundamental study that one cannot see at present just how it is to be tackled.

Then there is the puzzling subject of the relationship between viruses and insects, very clearly and succinctly discussed in this book. Is there really an intimate relationship between the two, and do plant viruses actually multiply inside their insect vectors? Or is the whole question merely one of particular feeding methods whereby the virus is introduced into the right plant tissues, and of particular anatomical conditions in the insect which must be fulfilled to permit of adequate virus storage? All these questions need answering, and although we have a mass of data concerning insects and plant viruses, we really know very little about their relationships.

Then take the question of the origin of viruses dealt with in Chapter 16. The author cites the paracrinkle virus present in all King Edward potatoes, also recently discussed in *Nature*[1], and suggests that it is possible that viruses may have arisen, only to disappear with the death of their host plant. Presumably, however, if such viruses can be transmitted by insects, they would be spread to other plants and a new virus disease would be perpetuated. Unfortunately, or perhaps fortunately, so many of the new viruses which do come to light are not apparently insect-borne.

There is no doubt that previously undescribed viruses do appear in plants, even under controlled conditions, and these would undoubtedly have been lost again if they had not been carefully propagated by artificial means. There is the interesting case of tomato bushy stunt virus, which suddenly appeared in a few tomatoes in the Bristol area and one or two other localities in 1935 and then disappeared again completely until the summer of this year, when it was re-discovered affecting tomatoes near Worcester. No insect vector has ever been discovered for this virus nor has it been found occurring naturally in any other host plant. Incidentally, this virus was first purified as true three-dimensional crystals by the author and N. W. Pirie, and the purification of viruses and the properties of purified virus preparations are well discussed in Chapters 8, 9 and 10.

The author has made a special study of the serological reactions of plant viruses, and he discusses this aspect very thoroughly in Chapter 7. He also advocates in Chapter 14 a classification of plant

viruses based on their serological relationships, in a severely critical review of present systems of nomenclature and arrangement. Undoubtedly a classification of viruses based on some such scientific basis as serological relationships would be ideal. Unfortunately the fact that a very large number of viruses cannot at present be studied by serological methods renders such a classification for the time being purely academic.

Mr. Bawden is to be congratulated on a very good book which presents an authoritative survey of the present status of plant virus research.

KENNETH M. SMITH.

## INORGANIC NUTRITION OF PLANTS

**Lectures on the Inorganic Nutrition of Plants**
(Prather Lectures at Harvard University.) By Prof. D. R. Hoagland. (A New Series of Plant Science Books, Vol. 14.) Pp. xii+226 (28 plates). (Waltham, Mass.: Chronica Botanica Company; London: Wm. Dawson and Sons, Ltd., 1944.) 4 dollars.

THE present volume embodies the texts of seven lectures, five of which were originally delivered at Harvard University under the Prather Lectureship. It is fortunate that these lectures have been printed, for this is undoubtedly a valuable contribution to the literature of the subject. It carries, of course, the limitation of the form of presentation. Prof. Hoagland explains in the preface that "this small volume cannot have any of the characteristics of a monograph or a text"—and such it has not. But it does provide a discursive survey of a field of investigation in which cohesion is frequently obscured by the rich variety of topics that the subject is commonly held to embrace, and in which, therefore, such a survey is particularly valuable.

The variety of content probably makes the subject difficult to discuss comprehensively, and to this, no doubt, must be attributed the fragmentary character of the discussion. But the difficulty is not relieved by the particularly generous view that the author takes of the implications of the term 'inorganic nutrition of plants'. The book begins with a discussion of soil conditions in relation to nutrient absorption, deals then with micronutrient elements, the absorption and accumulation of salts by plant cells, the translocation of inorganic solutes, exudation and root pressure, the growth of plants in artificial media, the relation of salt absorption to organic acids, and concludes with a chapter on potassium nutrition. In different connexions extensive reference is made both to the crystalline structure of soil colloids and to the synthesis of amino-acids. Inevitably within a text which is restricted to a hundred and eighty small pages of comparatively large print, the treatment of even the majority of these topics cannot be extensive, and must, in many instances, be unduly cursory. Moreover, in certain connexions the emphasis is unusual. The metabolic significance of potassium, nitrogen and zinc receives considerable attention, but there is little discussion of, for example, phosphate nutrition; and whereas the effects of individual elements are described, the interaction of the several nutrients in metabolism and growth is not treated in any detail.

These criticisms, however, are in any event not important, and may be irrelevant, since Prof. Hoagland writes: "the assumption was made that in lectures of the present type and objective the writer should emphasize the work with which he has had most direct contact". That work represents a distinguished body of contributions, and the prominence that it receives necessarily emphasizes certain recent important developments both in the elucidation of the mechanisms of well-recognized phenomena, and in the elaboration of new techniques. The author and his school have devoted considerable attention to the processes of salt absorption, accumulation and translocation, and in relation to these the importance of the metabolic situation is developed in some detail; the particular implications of absorption from the soil are discussed; and valuable summaries are provided of the results of investigations based on the use of radioactive isotopes as tracers.

The text is adequately illustrated with figures and plates; it is also supplied with a number of tables which are difficult to decipher, the print and numerals being distressingly minute. Otherwise the print and lay-out are admirable.

R. BROWN.

## LOCAL GOVERNMENT FINANCE

**The Problem of Valuation for Rating**
By J. R. Hicks, U. K. Hicks and C. E. V. Leser. (National Institute of Economic and Social Research, Occasional Papers No. 7.) Pp. vii+96. (Cambridge: At the University Press, 1944.) 7*s*. 6*d*. net.

THIS paper is the second part of a study of the incidence and effects of local government taxation, the first part of which, "Standards of Local Expenditure", has already appeared and the third of which will round off and complete a work of great interest and considerable importance for those who are, or shall be, occupied in local planning and reconstruction. It may well be the most significant of the three; for it examines and discusses the key problem of local finance—the variation in the burden of rates from one area to another due to the absence of uniformity in the standards employed for valuing rateable property. It is an old problem, the essentials of which were being studied by a Departmental Committee on Valuation for Rating set up in 1938 which had not completed its task at the outbreak of war. The authors were fortunate in having been permitted access to returns collected for the use of this Committee. They are, in consequence, able to offer reliable evidence confirming conclusions hitherto based on surmise or impression only.

Briefly, the conclusions are that rating valuations are inaccurate, that, therefore, they are not an index of the true wealth of an area, and the anomalies resulting from this stand in the way of effective assistance by means of grants to the poorer areas. As at present administered, rates are a bad tax. On the other hand, their abolition and replacement by an alternative would involve a fundamental alteration in the whole basis of local government. This is not practical; but some measure of reform is imperative, and a beginning might be made with the regularization of the assessment of rateable values. It is generally understood that the Rating and Valuation Act of 1925 had this, among other aims, in view; but the uniformity in valuation practice which was anticipated was not realized. In 1938,

thirteen years later, the condition in this respect could only be described as chaotic. The remedy suggested is the transference of the responsibility for valuation to a central authority which, helped by a court of appeal, would in the course of time evolve a national code of rules. The authors proceed to examine the difficulties that would arise in any attempt at speedy reassessment from the fact that, under the present law, rates vary nearly proportionately with gross values and that, to prevent them from falling on the poor to an extent felt to be intolerable, there is under-assessment of 'poor' houses in comparison with 'wealthy' houses. There is also the problem arising from the prevalent tendency to value new houses at a relatively lower level than old houses. Much time would elapse before the proposed new authority could straighten out imperfections; for a new system must grow slowly.

It was not part of the authors' plan to suggest major innovations or reforms in the finance of English local government. This is to be regretted; for it is no secret that small and poor authorities are viewing with dismay the addition to the commitments threatened or imposed upon them by the new Education Act and similar measures. Rumour has it that only minor alterations in boundaries will be made as the result of government inquiries now proceeding and that the larger and wealthy areas will be left substantially untouched. It is difficult to escape the conclusion that the size and functions of local government units call for drastic revision if the present financial system is to continue.

J. G. SMITH.

## FLUORESCENCE AND PHOSPHORESCENCE AND THEIR APPLICATIONS

### Luminescence of Liquids and Solids

And its Practical Applications. By Peter Pringsheim and Marcel Vogel. Pp. x+201. (New York: Interscience Publishers, Inc.; London: Imperia Book Co., Ltd., 1943.) 4 dollars.

THE study of luminescence, particularly the luminescence of solids, has undergone profound changes during the last ten years. Before that time, knowledge of energy states and energy transfers in the liquid and solid states was exceedingly meagre; the subject of luminescence as a whole had a very uncertain theoretical basis. The recent advances have perhaps been more striking in the case of solids, and this can be traced in great part to the stimulation which the subject received from A. H. Wilson's papers on semi-conductors. Almost simultaneously, some of the newer discharge lamps began to pass from the laboratory to the manufacturing stage. The new mercury discharge lamps were at once a challenge to those interested in the luminescence of solids; for the emission spectrum of these lamps contained a plentiful proportion of near ultra-violet radiation, coupled with a deficiency of emission at the red end of the spectrum. Lamp manufacturers in many parts of the world successfully met this challenge, and greatly improved techniques for the preparation of luminescent solids were developed, with results that most of us are now familiar with. At the same time the more fundamental aspects of the subject received renewed attention (see, for example, the Faraday Society's Discussion on Luminescence, 1938), and it was clear that the subject was emerging from a period of empirical research previously dominated by the Lenard school, and documented, for example, in vol. 23 of the "Handbuch der Experimental Physik".

Prof. Pringsheim is well known for his original work on the fluorescence of liquids and vapours, and also for his earlier book "Fluorescenz und Phosphorescenz", the third edition of which was published in 1928. This book undoubtedly gave the best available physical approach to the subject, but from the modern point of view it was sadly out of date, and scarcely comprehensive. The present reviewer had hoped that the new work by Pringsheim and Vogel would in effect be a completely revised edition of the earlier German monograph. In this it must be confessed he is disappointed; the new volume is a popular exposition of the subject, and particular emphasis is laid on the applications. Within these self-imposed limits, the authors have produced a useful survey for the general reader; it cannot be said that the book will add much to the knowledge of specialists.

The first part of the book is concerned with the physics of luminescence. After a brief introduction to the historical and theoretical aspects of the subject, experimental technique, materials and their properties are considered at length. A chapter is also devoted to the rapidly growing subject of fluorescence analysis. Fluorescent paints and screens for various purposes are also considered, but some of the later illustrations are more reminiscent of the cheaper type of commercial brochure than would have been anticipated from the hands of the senior author. Figs. 56, 57 and 59 give, respectively, external views of a cathode-ray tube, a television receiver and an electron microscope; they do not appear to serve any particularly useful purpose.

It is to be hoped that Prof. Pringsheim will now write the book we have been waiting for.

J. T. RANDALL.

## GERMANO-POLISH PROBLEMS

### Teuton and Slav on the Polish Frontier

A Diagnosis of the Racial Basis of the Germano-Polish Borderlands and Suggestions for the Settlement of German and Slav Claims. By Lt.-Col. G. R. Gayre. Pp. 76+18 plates and 41 maps. (London: Eyre and Spottiswoode (Publishers), Ltd., 1944.) 8*s.* 6*d.* net.

LIEUTENANT-COLONEL GAYRE has written a short study of the Germano-Polish problem in terms of physical and social anthropology. He has sought indeed to give as much information, explanation and comment by means of cartography as through the letterpress, since the book has more than forty maps and diagrams.

Some of the cartographical material is interesting in that the work of foreign scholars has been reproduced for the benefit of English readers for the first time. Some maps, however, are spoiled by the form of reproduction, for example, Nos. 4, 5, 16 and 31, in which the type of the place-names and legend has been reduced so much that the result is illegibility.

The descriptions of geographical background, of the physical characteristics of the peoples concerned, and of their culture, are not without interest, nor

are the final comments on possible post-war frontiers. But the reader who has had the opportunity of studying the Germano-Polish question is left at the end with a feeling of disquiet. He has the impression that factual information has been chosen to make yet another theory on the vexed problem of Central Europe, but that even an outline tale has not been told in proportion. Any account of the Germano-Polish settlement areas, for example, should contain much more emphatic comment upon the loess strip between the Hercynian Highlands and the glacial plain than is present in Lieutenant-Colonel Gayre's study. Moreover, the story of Teuton-Slav relations is incomplete from the point of view of the anthropologist without some treatment of the migrations of the Dark Ages. It is misleading to take it up at the stage when the peoples of Central and Western Europe were beginning to achieve some geographical fixity, especially when early history is made the foundation of political opinion on current events. Finally, although one may agree with the author that too great an importance was attached to linguistic divisions in the re-drawing of frontiers after the War of 1914–18, it is difficult to believe that physical anthropology is going to prove a safe guide to demarcation after the present one.

Lieutenant-Colonel Gayre makes a point at the end of his study which is worth close attention. Before the first World War the disparity between the German and Polish birth-rates was noticeable, and the greater increase of the Slavs has continued between the two Wars. The Germans may have needed *Lebensraum* in the sense of greater economic opportunity, but they wanted living space in the literal sense much less urgently than the Poles. The eager concentration of the Germans on penetration into Eastern Europe came rather from demographic unease, an instinctive dread of the multiplying Slavs, than from territorial need. The immense loss of German man-power in the present War suggests that pressure on living space in Germany will be still less, once the actual devastation of war is repaired. It remains to be seen whether the terrible destruction of life and material well-being in Poland will affect the demography of that country only temporarily or permanently.

It is scarcely the fault of the author if the development of the 'art' of war in the fifth year of this struggle makes arguments on frontier demarcation from the strategic point of view seem a little irrelevant.
H. G. STEERS.

# ELEMENTARY ZOOLOGY

## Animal Biology

By Dr. A. J. Grove and Dr. G. E. Newell. Second edition. Pp. viii+678. (London: University Tutorial Press, Ltd., 1944.) 16*s*.

THIS book is already well known, and young people coming to the study of zoology for the first time will find in this second edition an account of animal structure which is welded with the elementary facts about the animal's physiology and relation to the environment. The whole fascinating story is told in words which create enthusiasm and stimulate further study and reflection. Older readers who were students when morphology was the main preoccupation of zoology will appreciate this book no less. It is easy to neglect or even to deprecate the beauty and significance of animal architecture, but this book avoids this error and also the older one of emphasizing it too much. By it the beginner will be prepared for the wider conceptions of modern biology.

The changes in this new edition are mainly amplifications of certain sections and additions wherever these are necessary to bring the book up to date. An outstanding feature of the book is its excellent diagrams, which are much better than those usually found in books of this kind. Some of these diagrams have been re-drawn; others are new. Eight new photographic illustrations of the earthworm and crayfish have been added; but some readers will wish that the space occupied by these had been given to really good and characteristic photographs or drawings of the animals dealt with in the chapter on the animal's background or to a better illustration than the one of the rabbit on p. 234. These would have helped other illustrations to remind the student that a diagram is only an interpretation of living structure and not a representation of it. Captious critics may detect one grammatical error, evidently missed in the proofs, namely, "The life-histories" . . . of nematodes . . . "is frequently complicated" on p. 628. Nematoda are classified as a phylum and not as a class of the Nemathelminthes. Although their uniformity of structure in spite of their success in a wide variety of habitats is noted, their great influence on the health of man and on his food supplies entitles them, some consider, to a more adequate treatment, even in a book for the beginner, than they receive here. Nor are the paragraphs on the pathology and control of the flatworm parasites adequate.

But these are, perhaps, minor criticisms. The beginner will not go far wrong if he selects this book, especially if he adds to it, for the sake of its philosophical and physiological outlook and the illustrations designed to resemble what is actually seen under the microscope, Woodger's "Elementary Morphology and Physiology for Medical Students". But, whatever books he uses, the student should never forget the advice given in the preface to the first edition of this book, namely, that the study of the animal is the essential thing, that a living animal is better than a dead one and that a dead animal is better than no animal at all. If this book is intelligently used, the student will not come excitedly to his teacher, as he has been known to come, with the information: "There's something wrong with my rabbit; it isn't like the book".
G. LAPAGE.

# ORGANIC CHEMISTRY

## Principles of Organic Chemistry

By Sylvanus J. Smith. Pp. viii+570. (London: Macmillan and Co., Ltd., 1944.) 15*s*.

THE author states in the preface that the object of this book is to provide a course in organic chemistry which a student may be expected to cover in about three years from starting the subject, and hence, quite rightly, the book does not follow rigidly the syllabus of any particular examining board.

The first two chapters give a brief survey of the determination of formulæ and physical properties, together with a discussion of isomerism and the electronic theory of valency. In view of the scope of the book it is a pity that no mention is made at this stage of the phenomenon of resonance; and it is unfortunate that a misleading structural formula has

been given to the ammonium ion, which has been repeated later on (pp. 176–177) for the substituted ammonium salts.

The paraffins and their aliphatic derivatives, such as alcohols, ethers, aldehydes, ketones, fatty acids and amines, are described in the following chapters; a pleasing feature of which is the number of graphs that have been given to show the relation between the molecular weights of homologues and their melting and boiling points.

After a short description of the olefines and acetylenes and their derivatives, a fairly detailed account is given of the dibasic acids, together with derivatives such as urea, ureides and diureides. The amino-acids and proteins are discussed in the same chapter as the hydroxy and keto acids, which is not a very suitable arrangement. The ultracentrifuge method of measuring the molecular weights of proteins is described, and the theory of the method is given in an appendix at the end of the book. A detailed account of the structure of the chief carbohydrates and of the reactions of the cyanogen derivatives and organo-metallic compounds is given.

Benzene and its more important derivatives are described adequately on the whole, although the account of the resonance effect on substitution in the benzene ring is too brief to be clear.

The heterocyclic compounds are illustrated in the main by a discussion of furane, furfural, pyrrole, indole, pyridene and quinoline. The terpenes and alkaloids are described in the closing chapters of the book, which also contains logarithm tables and a good index, as well as a wide selection of questions at the end of each chapter.

One of the outstanding features of the book is the large number of structural formulæ which have been given; but it is very unfortunate that apart from a few obvious misprints, several of these formulæ are based on obsolete structures; for example, ethylene ozonide, the Grignard reagent, and penta-covalent nitrogen in alanine, glycine, betaine, sulphanilic acid, etc. In this connexion it is surprising to find that although the modern formula for the nitro-derivatives has been given, the nitro-compounds are represented for the most part by the classical penta-covalent nitrogen structure.

Another criticism is that too much space has been devoted to obsolete or semi-obsolete processes, and many reactions which are now of far-reaching importance are omitted or given scanty treatment. Thus, the manufacture of methyl alcohol from wood spirit is described prior to, and in more detail than, the carbon monoxide – hydrogen method; while it is implied that the only technical preparation of acetone is from pyroligneous acid. No mention is made of the chlorination of acetylene and the subsequent preparation of useful solvents; and the polymerization of the olefines, now of supreme industrial importance, is dismissed in three lines.

The statement (with the accompanying equations) that the formation of an alkyl halide from an alcohol and hydrogen hydracid "structurally resembles the formation of a metallic halide from an alkali:

$$C_2H_5OH + HCl = C_2H_5Cl + H_2O,$$
$$NaOH + HCl = NaCl + H_2O."$$

will make the reader rub his eyes and wonder whether the theory of the complete ionization of strong acids and bases has been discarded.

On the whole, I do not consider that this book is suitable for use as a school text-book; but portions of it may be useful to university students, provided that due regard is paid to the criticisms made above. The book is printed in clear type on paper of good quality, and the binding is excellent for a war-time publication.

A. C. CAVELL.

# PSYCHIATRY FOR EVERYMAN

**A Handbook of Psychiatry**

By Dr. P. M. Lichtenstein and Dr. S. M. Small. Pp. 330. (London: Kegan Paul, Trench, Trubner and Co., Ltd., 1944.) 16*s*. net.

DURING the past three years, a number of books dealing with psychiatry have been published. They have all been condensed and mostly very well done. The present book by Lichtenstein and Small of New York presents the subject from a rather different aspect. It is described as "having been prepared not only for students of psychiatry, but for all those whose work brings them into contact with mentally disturbed persons". It is very well done, and will serve the purpose for which it was prepared extremely well. It will probably appeal most to the social worker and those whose work is almost entirely concerned with the mentally abnormal, but there are many relatives of those mentally disordered who might with great advantage read, mark and learn. Their attitude towards both patient, nurses and medical men might change greatly.

It is difficult to select any one chapter of the book as better done than any other. Naturally in a work so condensed and simplified it is difficult to deal adequately with subjects like psychotherapy and general principles of psychiatric therapy, but the reader will be able to realize how much progress has been made and is still being made in treatment in what is admittedly the most difficult branch of medicine.

It is a pity that in discussing the etiology of schizophrenia the authors do not mention the work of Hemphill and Reiss at Bristol on biopsy of the testicle. This work is confirming the general direction taken by the views of Mott put forward in 1922, which were afterwards rather discredited. The results of biopsy show very definite changes in the testicle. The modern view of paranoia does not accept the presence of hallucinations as part of the clinical entity. Both pellagra and beriberi are surely vitamin deficiency diseases and *not* infectious in origin.

We would like to see included under the senile disorders, Pick's disease. Alzheimer's disease is included as a pre-senile condition, and Pick's disease should be mentioned with it. It is a mistake to say that with electric shock treatment the patient has a complete amnesia after the experience. Some patients remember everything prior to the unconscious phase, and quite a few have a very decided objection to the treatment, often amounting to a definite fear.

Having regard to the amount of space devoted by the popular Press to the subject of psychosurgery, the section dealing with this most fascinating development in modern treatment might well have been considerably expanded. The mortality-rate in Great Britain is distinctly less than the 4–5 per cent quoted by these authors.

The book is well produced, very easy to read, and we recommend it heartily as an introduction to that most fascinating study—human abnormality.

G. W. T. H. FLEMING.

# INTERNATIONAL STATUS OF CRYSTALLOGRAPHY, PAST AND FUTURE*

By PROF. P. P. EWALD

IN the period between the War of 1914–18 and the beginning of the present War, crystallography experienced a rejuvenation, and in its new form of X-ray crystallography it has once more attained a central position bordering on many fields of promising development. While in its early days crystallography had contacts mainly with mineralogy, geology and crystal optics, at present its most intimate links are with atomic physics, chemistry, metallography and increasingly with engineering and industrial production. In fact, crystallography is forming the background for most problems concerning the solid state of matter. Compared to its advances on the newly won ground, its recent interactions with mineralogy and geology have been rather limited, but this may change in the future. It is recognized that crystallography stands in respect to its methods nearest to physics, for it originated as a part of physics; but the most urgent present demand for its methods and data comes from chemistry.

The early spread of research on crystals from the physical to the mineralogical and chemical laboratories in the first half of the last century prevented a consolidation of crystallography as such. It became, as it were, suspended between the three dominant disciplines. Even to-day, few universities have chairs of crystallography; crystallographic instruction is mostly given in the departments of mineralogy, but the departments of physics and of chemistry usually also give the bare minimum of crystallography which is needed for applications. In no country does there exist a learned society solely for the promotion of interest in, and knowledge of, crystallography. The results of crystallographic research have to be collected from physical, chemical, physico-chemical and mineralogical journals, besides being dispersed in the publications of learned societies. This was so before the days of structural crystallography; since then, biological, engineering and industrial journals have been added to the dispersal area of crystallographic work.

Nevertheless, there is a close connexion between the various sides, pure and applied, of crystallography. The underlying laws and the methods of observation and interpretation are the same, and progress made in one field may immediately benefit problems which seem altogether remote. The determination of unknown crystalline material from geometrical, optical or X-ray observations (to be mentioned again later on) shows the application of different methods to the same end; while the application of the same method in entirely different fields of research is exemplified by the X-ray determination of particle size and shape of clays, of metals and of catalysts.

The development of other subjects has led to their segregation from their original context. Astronomy and engineering have broken away from physics; physical chemistry, bio- and colloid chemistry from chemistry; there are societies devoted to the promotion of optics and acoustics, with the corresponding journals. This process of specialization, inevitable as it seems, is sometimes deplored as a disintegration of science. Should it not rather be looked upon as the formation of a new branch on the tree of science, which conveys the sap to a region hitherto not well provided for, a branch necessary for rounding off the shape of the tree as a whole? Crystallographic research might gain much by being clearly outlined as such and by being provided for by a Crystallographic Society with its own journal.

This idea is not new, as the history of the *Zeitschrift für Kristallographie* shows. It was a hundred years of development from Romé Delisle's first correct description of crystals to the foundation of this journal. Even then, in 1877, P. Groth could not venture to devote his journal to crystallography alone, but for financial and other reasons he had to make it a *Zeitschrift für Kristallographie und Mineralogie*. Fortunately, this foundation coincided with a time of rapid development, especially of chemical crystallography, and the editor, together with the great number of his students from all countries, contributed many important crystallographic papers, thus giving the *Zeitschrift* a bias towards crystallography. Groth's interest and experience ranged wide and were full of detail. This made his abstracts of crystallographic papers from other publications critical and stimulating, and he aimed at making them detailed enough to render the study of the original papers unnecessary to most readers of the *Zeitschrift*. From these reviews and from the hundreds of checks and corrections on the reported results which he got his untiring collaborators to carry out, there arose the five volumes of "Chemische Kristallographie", a monumental summary of the first great period of crystallography.

Groth edited fifty-five volumes of his *Zeitschrift*; then, in 1921, he handed it over to P. Niggli, of Zurich. At the same time a new publisher, the Akademische Verlagsgesellschaft, acquired the *Zeitschrift*. Niggli remained chief editor until 1940; owing to his not being subjected to the Nazi *Reichsschrifttumskammer*, and owing to the international connexions of the *Zeitschrift*, it was possible to maintain for it a freedom in editing which most scientific journals in Germany had to sacrifice in order to survive.

When Niggli took over, the time had at last come when mineralogy could be dropped from the title, which now read *Zeitschrift für Kristallographie* (*Kristallgeometrie, Kristallphysik, Kristallchemie*). Many of the papers offered to the *Zeitschrift* for publication, especially crystal structure determinations, came from abroad, and often after it had been found impracticable to obtain their full publication in the overcrowded physical and chemical journals, the bulk of the readers of which were not interested in the details of the work, or even competent to judge them. The absence of journals devoted to crystallography gave rise to great inconvenience, especially in the English-speaking countries. It was therefore decided to facilitate the publication of structural work in the *Zeitschrift* by 'internationalizing' it; that is, by accepting papers in French and English as well as in German. At the same time, prominent crystallographers all over the world were asked to act as patrons by allowing their names to figure on the title page and by entrusting the *Zeitschrift* with the publication of suitable parts of their research. The liberal answer to this request, and the use to which this mode of publication was put, fully justified the action taken. It was somewhat unfortunate that the steady but slow increase in number of subscriptions

* Part of an evening lecture delivered at the meeting of the X-ray Group of the Institute of Physics at Oxford on March 31, 1944.

could not balance the rapid increase in volume of production without imposing a heavy burden on the subscribers.

The *Zeitschrift für Kristallographie* never held, nor attempted to hold, a monopoly in the publication of structural work. Much of this went to the proceedings of learned societies, and much to chemical, physical and technical journals. This will always be so, as it is not easy even to define the class of work which from a rational point of view should go to a journal of crystallography rather than to any related journal. The same difficulty, however, arises between general and physical chemistry or radio engineering and physics. The decision to publish a particular piece of research in one journal rather than in another depends, apart from more personal grounds, on the nature of the research and on the public which the journal can be expected to reach. The aim of any scientific publication must be to reach those who are most interested in the paper and most competent to judge its merits. The fluidity of the boundaries between subjects is no argument against devoting a journal to any one of them.

The countermeasure to this inevitable centrifugal tendency of scientific publication lies in a reliable abstracting service. Owing to the fact that crystallography is suspended, as it were, between many acknowledged and firmly organized sciences, abstracts of crystallographic papers are to be found in some twenty abstracting journals in English, French and German. But with few exceptions no clear outline of the method and results of these papers can be gained from any one of the abstracts. Groth's ideal of fully summarizing the results quoted in the paper abstracted has been abandoned, and abstracts in most cases merely indicate the type of work presented in the paper.

Various ways were tried in the *Zeitschrift* of returning to the Groth type of abstract. For the limited field of structure determinations it could be attempted in the 'Strukturbericht', thanks to liberal financial aid given by the Notgemeinschaft der Deutschen Wissenschaft. As regards the entire field of crystallography, however, the attempts failed. Not only was the number of papers so great that the abstractors were unable to keep up with them, but also the variety of the work contained often in a single paper demanded abstracting under different headings and from widely diverging points of view; finally, the range that had to be covered to satisfy all those interested proved prohibitive from the point of view of cost to the reader. After trying out other systems, a classified collection of titles was all that could be produced. This, however, is very nearly contained in *Science Abstracts*, *Chemical Abstracts*, *Physikalische Berichte*, *Zentralblatt*, etc.; even if their classification is not quite so convenient as one drawn up for the purposes of crystallography, the gain is not worth paying the price of re-collecting and re-publishing the catalogue of titles.

A similar situation arises in other semi-independent parts of physics and chemistry, such as geophysics or colloid chemistry. It leads to a great amount of duplication of abstracting work. The problem of handling research work from the many points of view, such as methods, results, substances and properties, is so important, and at the same time so difficult, as to require a concerted effort on the part of all those interested; the methods of approach might well form the subject of further regional and international discussions.

Pending a better solution of this general problem, crystallographic research may best be reviewed and collected by an extension of the method adopted in the *Annual Reports of the Chemical Society* or in *Reviews of Modern Physics*. Here no completeness is aimed at, but selected topics are reviewed by particularly competent workers. By changing the subjects of the reports, a fair survey of the whole field is obtained in due course.

Apart from the tasks of publication and abstracting, the development of crystallography after the War of 1914–18 brought some other problems to the fore which required international settlement. The simpler crystal structures had been more or less explored by 1924, and the use of the theory of Schoenflies-Fedorow became imperative. Niggli, Astbury and Yardley, and Wyckoff had adapted this theory to practical requirements, each in their own way, with different origins and axes of the space groups, different symbols in the drawings and different items listed. Text-books which appeared had to choose between two evils: either to repeat all the results, if not the derivation of space groups, or to be quite incomplete for practical work. The preparation of standard tables of space groups was an obvious desideratum. The occasion to discuss it formally arose when, after a conference on crystal structure arranged by the Faraday Society in 1929, Sir William Bragg convened a meeting of the many crystallographers then present in London. Three committees were set up at this meeting to report (*a*) on the abstracting scheme, (*b*) the preparation of tables, (*c*) nomenclature. Their reports, delivered in the course of the next year, were published in the *Zeitschrift für Kristallographie*. The Tables Committee, after substantial preparation by correspondence, met in Zurich in 1930 and decided the details of the tables and the distribution of work among the British, American, French, German, Dutch and Swiss authors volunteering for it. These "International Tables for the Determination of Crystal Structures", edited by C. Hermann and published by G. Bornträger in conjunction with firms in the various countries, appeared in 1935, and were subsidized by the International Union of Physics and by many learned societies in the contributing countries. They have since found wide application for structure determinations.

One of the successful innovations in these Tables was the replacement of the conventional Schoenflies notation of space groups by a more rational one, developed by C. Hermann and Ch. Mauguin, which has a direct bearing on the symmetry, and therefore on the actual determination of space groups from X-ray data. Thus the recommendation of the Nomenclature Committee was incorporated in these Tables.

A further occasion for an international discussion was afforded by the International Congress of Physics, held under the auspices of the Union of Physics in London in 1934, one half of which was devoted to problems of the solid state.

No description of international relations in crystallography could overrate the influence of the two great British schools and centres of research, at the Royal Institution, and at the University in Manchester, both associated with the name of Bragg. Here students and scholars from all over the world received training and inspiration for crystallographic work; they made contacts among each other which wove them into a friendly international guild.

The present War has temporarily disrupted most of this texture, but it is certain that the desire for even closer international co-operation will return after the War in a subject so wide in extent and developing so quickly. A prelude to this is the regional consolidation of those interested in X-ray crystallography. In the United States, a Society for X-ray and Electron Diffraction was founded in 1940; its present membership is 350. In Britain, an X-ray Analysis Group of the Institute of Physics was formed in 1943, based on the success of several conferences on the subject which had been arranged by the Institute of Physics in the preceding years and which had shown attendances up to two hundred. In Germany the Deutsche Gesellschaft für technische Röntgenkunde arranged yearly conferences from 1929 onwards which dealt largely with the analysis and testing of materials by means of X-rays. Further regional or national organizations may be in existence or planned in other countries. They are to be welcomed, as they promote the interest taken in the subject, raise the standard of application and form a necessary stepping-stone for an international organization.

The desirability of forming, besides regional crystallographic societies, an International Union of Crystallography, should be clear, I believe, from past experience. Co-operation of all authorities is necessary to develop a subject with so many ramifications and applications to its optimum efficiency. In particular, the following topics seem to demand general agreement:

(1) *Publication.* It is undesirable that structural and other crystallographic work should be scattered in many journals, each of which only grudgingly concedes adequate space to it. A fair amount of concentration of this work in a single journal offers the obvious advantage of knowing where to look for it.

A journal like Groth's *Zeitschrift,* privately owned by a publisher, and therefore out of the control of the editors in important respects, is not ideal. It would be preferable to have a journal of crystallography owned by, and edited on behalf of, an International Union of Crystallography.

(2) *Archives.* The lengthy details of some structural work are of immediate interest only to the very few working on the same or closely related substances. It is unfair to make all the others pay for their publication. On the other hand, it is a generally accepted principle that only public tion of the details allows the necessary check on the author's work. As a way out of this quandary, it has been proposed to establish an archives for crystallography in which the full details submitted to the journal of crystallography would be kept in a form suitable for publication; anyone interested could obtain them at low cost on microfilm or in other photographic form. The manuscripts, as submitted to the editors of the journal, would have to give the complete argument, but on the proposal of the editors or the author certain parts of the details, mainly routine measurements, would be either relegated to the archives and replaced by a summary in the paper, or included in the paper at the author's cost.

These archives would also be used for depositing unfinished work of which only a summary description would appear in the journal.

(3) *Abstracts and Summaries of Crystallographic Work.* The collection of structural work and of phase diagrams could be carried on in conjunction with the archives and the journal. Summaries of experimental and theoretical work as proposed above could be arranged to appear. An important function of the Union would consist in representing the interest of crystallographers once the general problem of rationalizing the abstracting schemes in science comes to be discussed.

(4) *International Tables.* The first edition of these Tables is exhausted and a second edition should be prepared by pooling the experiences gained in the various laboratories where they have been in use. It is therefore desirable that the second edition should again be prepared by an international committee. Here also the question of property rights arises; it would be preferable to make the Tables the property of the Union, and to commission a publishing firm with the printing and distribution.

(5) *Analytical Tables of Crystals.* Various systems have been or are being worked out for determining unknown crystalline substances from geometrical, optical, or X-ray data (cf. J. M. Robertson, *Nature,* **154**, 350; 1944). These systems are still on a tentative scale, but it seems likely that a method of wide applicability will emerge, and with it the necessity for a systematic survey of all known substances. The detailed planning and the distribution of this work would best be done under the auspices of the Union.

(6) *General Tasks.* Lastly, a Union of Crystallography, represented regionally by its member societies, would act—to use an appropriate metaphor—as a nucleus of crystallization for the whole system of research on the structure and properties of matter in the solid and in related states. The Union and its members would be called upon to co-operate on particular problems with the Unions of Physics and Chemistry, with mineralogical and biological societies, and with those for testing materials. In matters of scientific instruction and of planning of research, the Union might arrive at well-considered recommendations in its field. Finally, the Union might act as a juridical person in matters requiring the handling of money.

A word should be said about the use of the term 'crystallography'. American and British societies referred to earlier have avoided this term in their names and have stressed instead the method of observation they wish to promote. The main reason for this may have been the fact that X-ray and electron diffraction methods are being applied also to substances which are not crystals, such as fibres, proteins, colloids, even liquids and the molecules in gases.

While the titles chosen give a clear indication of the main present activity of the respective societies, I would suggest that they imply a restriction which will ultimately be either abandoned, or prove undesirable. For any particular method, after having been applied for some time, tends either to become a routine method of observation, and as such of minor interest, or continually to be merged with other methods supplementing it from fresh sides. In the case of the X-ray method, this latter happened first when W. L. Bragg drew up a list of atomic radii. Later optical and magnetic observations, and the principles of atomic physics and of crystal chemistry which were being established, were added to the armoury supplementing the diffraction method. For how long will it be true that the main interest of the two societies lies in the diffraction and not in the supplementary methods? Are not many of their members interested mainly in applying the results gained by diffraction methods to the elucidation of

chemical, mechanical and physical properties? Is it not one of the main aims of these societies to link up X-ray diffraction with whatever chemical or physical methods seem promising to supplement it? The present circumscription of the societies' activities is decidedly too narrow.

'Crystallography', in its original meaning, does not, it is true, include the entire field of application of diffraction methods. But it covers the main field even then. 'Leptology', which Rinne coined for fine structure (λεπτός, fine), would be preferable to 'crystallography', but the word has not been generally introduced, and this might not be a good occasion to plead for it. Unless something new is adopted, however, 'crystallography' will have to be used in a wider sense than originally intended, so as to cover substances which for some purposes may be regarded as inferior forms of crystals; in them the arrangement of the atoms or molecules, while showing some kind of regularity, departs further from perfect three-dimensional symmetry, homogeneity and periodicity than in the actual piece of quartz to which the name of crystal was originally applied. The remaining regularity may, however, suffice to make profitable a close connexion of substances regarded from this aspect and of the old-time crystals, and it is this enlarged field which the term 'crystallography' should be understood to cover.

## 'PHENOXETOL' AND OTHER ANTIBACTERIAL SUBSTANCES

THE offensive against pathogenic micro-organisms continues to succeed, and a number of recent articles upon antibacterial substances indicate the widespread interest in them among non-medical workers and also the value of co-operation between scientific men—and especially biochemists—and the medical man. In a leading article last year the *Lancet* (781, June 19, 1943) discussed the evaluation of wound antiseptics and directed attention to Prof. Garrod's review of the recent advances that have been made (*Brit. Med. Bull.*, **1**, 48; 1943). W. A. Altemeier (*Surgery, Gynaec., and Obstetr.*, **75**, No. 6; 1942) has published a collective review of the bacteriology of war wounds (see *Bull. War Med.*, **4**, 60; 1943). Numerous articles in the *British Medical Journal* and the *Lancet* keep us continually informed of progress of research on this subject. Referring to the work in Sydney, Australia, of A. Albert, J. E. Falk and S. D. Rubbo (*Nature*, **153**, 712, June 10, 1944), the *Lancet* (148, July 29, 1944) discusses the antibacterial action of organic arsenicals such as arsphenamine and neoarsphenamine. Interesting also is the work on sulphasuxidine (succinyl sulphathiazole), some of which is hydrolysed in the lower bowel with the release of free sulphathiazole, which is effective in intestinal infections. It is stated in the *Lancet* (544, April 22, 1944) that E. J. Poth and C. A. Ross (*Proc. Amer. Soc. Pharmacol. Fed.*, Baltimore, **2**, 89; 1943) claim that sulphathalidine (phthalyl sulphathiazole) is two to four times more bacteriostatic than sulphasuxidine because it is more completely hydrolysed in the bowel. Combinations of sulphathiazole and proflavine in powder form have been recently successfully used by Prof. J. Macintosh and his colleagues (*Lancet*, 591, May 6, 1944) and by Major G. Y. Feggetter (*ibid.*, 593). Lieut.-Colonel J. W. Bigger (*Lancet*, 142, July 29, 1944) records his work on the synergic action of penicillin and the sulphonamides.

Penicillin is, of course, always in the picture. Sir H. W. Florey (*Brit. Med. J.*, 169, Aug. 5, 1944) gives yet another survey of progress of work on its action, and the same issue of that journal contains articles on the use of penicillin in ophthalmology and in acute empyema and on its combination with sulphonamides for the treatment of infantile gastro-enteritis. J. S. Jeffrey and Scott Thomson (*Brit. Med. J.*, 1, July 1, 1944) give their experience of the treatment of battle casualties in Italy with penicillin, and in the same issue (p. 15) a leading article discusses an American symposium on the uses of penicillin. In the *Lancet* (44, July 8, 1944) W. D. Jeans, J. S. Jeffrey and K. Gunders record their treatment in Italy of four cases of smallpox with penicillin. The pustules in these cases contained *Staphylococcus aureus*, and secondary infection must, these authors think, be responsible for much of the toxæmia in the later stages of the disease. The penicillin treatment was followed by marked improvement, and three of the patients survived, including one who had not been vaccinated. Most of the penicillin used in the Mediterranean theatre of war and for research purposes in Great Britain has been supplied by British manufacturers (*Brit. Med. J.*, 186, Aug. 5, 1944), who are now increasing their production of it: but we owe to the United States the solution of its large-scale production and the consequent saving of the lives of many British and American wounded.

Penicillin is, of course, active only against certain species of bacteria. As Prof. Garrod states (*Brit. Med. Bull.*, ii, 2, 1944), most of the species susceptible to it are Gram-positive, and these include the pyogenic cocci Staphylococcus, Pneumococcus and *Streptococcus pyogenes*, the gas gangrene group of organisms and those of anthrax and diphtheria. The tubercle bacillus and almost all the Gram-negative bacilli, including the typhoid-dysentery group and *Brucella, Hæmophilus* and those common invaders of wounds *Proteus* and *Pseudomonas pyocanea*, which produces blue pus, are resistant to penicillin; but the Gram-negative *Gonococcus* and *Meningococcus* are susceptible to it. There is great need, therefore (*Lancet*, 185, Aug. 5, 1944), for a substance which will control Gram-negative organisms. In the same issue of the *Lancet* (p. 175) is an article by H. Berry on the antibacterial action of ethylene glycol monophenyl ether, to which the name 'Phenoxetol' has been given. Prof. A. A. Miles, in his interesting Sydney Ringer lecture at University College Hospital Medical School on the epidemiology of wound infections (*Lancet*, 809, June 24, 1944), points out that Sir Alexander Fleming's work on the bacteriological history of an infected war wound has been abundantly confirmed. Spore-bearing and intestinal coliform bacilli predominate in the first phase; they are replaced by pyogenic cocci in the second phase; and in the third phase these cocci persist and flourish. To them may then be added *Pseudomonas pyocyanea* and *Proteus*. Sulphonamides or penicillin will control the cocci, and this is a great advance; but the control of them may enable *Ps. pyocyanea* and *Proteus* to become more active, so that healing may be delayed. Berry claims that *Ps. pyocyanea* is particularly susceptible to 'Phenoxetol'. The addition of 10–20 per cent of serum in his *in vitro* experiments with it did not depress its action on this organism, and Berry claims that his *in vitro* tests suggest that 'Phenoxetol' might perhaps be used with penicillin, the acridine

compounds (for a discussion of some recent work on these and on some other wound antiseptics see the *Lancet*, 90, Jan. 15, 1944), the sulphonamides and the quaternary ammonium compounds. 'Phemeride' ('Phemerol') is one of these and its action on bacteria is discussed by C. N. Iland (*Lancet*, 49, Jan. 8, 1944). It resembles the related substance 'Cetavlon' (CTAB) (see J. M. Barnes, *Lancet*, 531, i, 1942, and R. Williams *et al.*, *Lancet*, 522, i, 1943). Further work on the antibacterial action of organic detergents such as these should be interesting. The toxic action of 'Phemeride' and another detergent called 'Zephiran' on the tissues, and methods of studying their toxic action are discussed in an annotation in the *Lancet* (188, Feb. 5, 1944), together with work on the effect of antiseptics on the metabolism of bacteria.

J. Gough, H. Berry and B. M. Still (*Lancet*, 176, Aug. 5, 1944) have tried 'Phenoxetol' on wounds, some of which were war wounds, and on burns, tuberculous cavities and cases of infected dermatitis. Most of the injuries treated were granulating areas associated with loss of skin and the need of skin-grafting; and these authors are studying combinations of 'Phenoxetol' with penicillin, the sulphonamides and the flavines. They conclude that a daily application of 2·2 per cent solution of 'Phenoxetol' in water reduced the infection with *Ps. pyocyanea* or eliminated it and resulted in clinical improvement. The addition of 5 per cent 'Phenoxetol' to the sulphonamide cream, which contains 'Cetavlon', devised by the Burns Unit of the Glasgow Royal Infirmary (see *Med. Res. Council War. Memo.*, No. 10) was tried *in vitro* and the results were encouraging. But the toxicity of 'Phenoxetol' and its absorption need further study. It would seem that the blue pus of *Ps. pyocyanea*, which was so common during the War of 1914–18 and did not then give rise to much anxiety, will shortly be controlled. It is proving, Gough and his colleagues state, an increasing nuisance in plastic surgery and skin-grafting. If future work discovers an opposite number to penicillin which will act with an equal efficiency on the Gram-negative organisms, then the labours of all those who are conducting the offensive against pathogenic micro-organisms will be well rewarded. Their problem will then be the reduction of the considerable laboratory work which is necessary before a choice of antibacterial substance suitable for each case can be made.

Regulations governing the manufacture of penicillin have been issued by the Government. The manufacture and use of crude penicillium filtrate was discussed by J. M. Alston in the *British Medical Journal* (654, May 13, 1944). A further note in the same journal (314, Sept. 2, 1944) reviews two articles in American chemical engineering journals which describe the great effort which has been made to produce penicillin in quantity; it required the expenditure of millions of dollars at a time (1940 and 1941) when the sceptic might have doubted whether the effort was justified. More than twenty factories have been erected at a cost of some 20 million dollars. The *British Medical Journal* (250, Aug. 19, 1944, and 317, Sept. 2, 1944) publishes notes on the use of penicillin for civilian cases, and the Ministry of Health has issued two memoranda on the use of penicillin now being issued to medical schools free of charge for the treatment of civilians. Next year there may be enough of it for all requirements. R. J. McNeill Love (340, Sept. 9, 1944) records one of a number of air-raid casualties to whom penicillin was given as a prophylactic with very gratifying results. In a leading article the *Lancet* (348, Sept. 9, 1944) further discusses the manufacture and use of penicillin and gives further references. A. Dolphin (*Brit. Med. J.*, 317, Sept. 2, 1944) has described the treatment of ten civilian cases at a meeting of the Fever Group of the Society of Medical Officers of Health, which was opened by Sir Alexander Fleming.

# LA SOCIÉTÉ FRANÇAISE DE PHYSIQUE

AT the meeting of the Physical Society on November 9, the president, Prof. E. N. da C. Andrade, welcomed some French physicists, members of the sister society, la Société française de Physique. He said: "We have here Prof. P. Auger, Prof. G. A. Boutry and Dr. S. Rosenblum. Through the kind offices of M. Boutry, professeur au Conservatoire national des Arts et Métiers and a fellow of our Society, I have received a brief account of the history of the Société since the outbreak of war. In it the president, Prof. J. Cabannes, records the lamentable fate of many members whose names are known to, and honoured by, all of us." Prof. Andrade then read out the following names of those who had died, the assembly standing:

"G. Dechêne, J. Farineau, H. du Mesnil du Buisson and J. Rossignol fell on the field of honour in the early battles.

"F. Holweck, who made his name famous by his pump and by other ingenious instruments, by his work on soft X-rays and by other notable researches, was murdered by the Gestapo; and J. Solomon, one of the most promising of the younger theoretical physicists, was shot by the German military authorities.

"Deaths that we have to deplore, some no doubt accelerated by the traditional brutalities of the Germans, are those of H. Buisson, H. Chipart, A. Dufour, A. Guillet, Victor Henri, J. Lemoine, Jean Perrin, Émile Picard and Pierre Weiss.

"Besides those who are known definitely to have lost their lives, there are others whose ultimate fate is unknown. H. Abraham, Eugene Bloch, G. Bruhat, L. Cartan, C. Sadron and J. Yvon have been deported to Germany, and we dare scarcely hope that they have received humane treatment there. Of Paul Langevin, who received in 1940 the highest honour the Royal Society has to give, the Copley Medal, we have no news, unless M. Boutry has something to tell us.

"Let me assure our French friends that although, as Mr. Eden said yesterday, 'People in Britain do not yet fully understand how complete, how merciless, how dastardly has been the devastation inflicted by the German armies in Allied lands as they withdraw', some of us here have some comprehension of German brutality. . . ."

Prof. Andrade added that, in spite of obvious difficulties, "all through the troublous days of the German occupation, zealous and courageous French colleagues have kept alive the science of physics in France. In June 1941 appeared a new publication, the *Cahiers de Physique*; and the first number of another new publication, the *Annales de Géophysique*, is at this moment in the press. We congratulate our French brethren on the success of their strenuous efforts."

Turning then to M. Boutry, Prof. Andrade said: "Au nom de la Physical Society je vous prie de bien vouloir saluer de notre part nos camarades de la Société française de Physique et de leur dire combien nous regrettons le lamentable sort de nos confrères, victimes du maudit système Nazi, ou plutôt allemand, combien nous espérons voir renaître dans toute sa gloire traditionelle et la France et la physique française. Nous avons remarqué avec la plus vive émotion comment, au milieu de tant de dangers et de difficultés, les physiciens français ont continué leurs travaux désinteressés. Tout ce que la Physical Society peut faire pour encourager et appuyer nos collègues, nos amis français, soyez assuré que ce sera fait. C'est pour nous un très grand bonheur de pouvoir désormais renouveler nos cordiales et traditionelles relations avec la Société française de Physique. Cher collègue, soyez le bienvenu."

In the course of his reply, Prof. Boutry said that Langevin is alive and well.

# OBITUARIES

## Sir John Ledingham, C.M.G., F.R.S.

SIR JOHN LEDINGHAM, emeritus professor of bacteriology in the University of London and a former director of the Lister Institute of Preventive Medicine, died in London on October 4 after a brief illness. John Charles Grant Ledingham—'a son of the manse'—was born in 1875, his father, the Rev. John Ledingham, being the minister of Boyndie, Banffshire. He was educated at Boyndie Public School, Banff Academy, and the University of Aberdeen, where he achieved many successes including the Simpson and Arnott Prizes and the Anderson Scholarship. He graduated with first-class honours in mathematics and physics, obtaining the B.Sc. degree with distinction. After a brilliant career in the Faculty of Medicine he obtained the M.B. degree with honours in 1902. Postgraduate study at the University of Leipzig and at the London Hospital followed, and in 1905 he joined the staff of the Lister Institute, being appointed assistant bacteriologist at Elstree and afterwards to the main institute at Chelsea. In 1909 he succeeded George Dean as chief bacteriologist, and on the retirement of Sir Charles Martin in 1930 he was appointed director of the Lister Institute.

During his tenure of the directorship of the Lister Institute, one of the most responsible posts in preventive medicine, Ledingham proved himself to be an able administrator and supervisor of research, while finding time to pursue his own researches on experimental studies of viruses and virus diseases. His investigations regarding the elementary bodies from vaccinial and smallpox material were a notable contribution to this subject. Later he studied the morphology and conditions of growth of the organisms of pleuro-pneumonia and allied conditions. Earlier in his career he carried out studies on the causation of purpura hæmorrhagica in man, on the mechanism of phagocytosis and on the epidemiology of the typhoid carrier state. He retired from the directorship of the Lister Institute in 1943. The University of London in 1920 had granted him the title of professor of bacteriology and, after his retirement, the title of emeritus professor was conferred on him in the present year.

During the War of 1914–18, Ledingham was in charge of the Bacteriological Department of King George Hospital and served afterwards in the Royal Army Medical Corps, with the rank of lieutenant-colonel, as member of the Medical Advisory Committee in the Mediterranean area and as consulting bacteriologist to the Forces in Mesopotamia. For these services he received the C.M.G. in 1918. He was elected to a fellowship of the Royal Society in 1921 and was knighted in 1937. He received the honorary degree of LL.D. from his own University of Aberdeen and also the honorary degree of doctor of science from the Universities of Dublin and Leeds. He was appointed a member of the Medical Research Council in 1934 and served on many expert scientific committees, being chairman of the Tropical Diseases Research Committee of the Medical Research Council and the Royal Society and a member of the War Wounds Committee in the present War. He was chairman of the British National Committee of the International Association of Microbiologists, president of the Second International Congress for Microbiology which was held in London in 1936 and was an honorary president of the Third (New York) Congress in 1939. He was largely instrumental in the formation of the National Collection of Type Cultures, sponsored by the Medical Research Council and domiciled at the Lister Institute, and was its director from its inception in 1920 until his appointment as director of the Lister Institute.

Some thirty papers were published under Ledingham's name or in collaboration with others during the period 1920–43; one of his outstanding achievements being a book written jointly with Sir Joseph Arkwright entitled "The Carrier Problem in Infectious Diseases", which was published in 1912. He was a noteworthy contributor to, and an associate editor of, the "System of Bacteriology" in nine volumes published by the Medical Research Council in 1930–31, as well as to the Council's "Treatise on Diphtheria". In 1924 he delivered the Harben Lectures in London and in 1934 the Herter Lectures at Johns Hopkins University, Baltimore.

Sir John Ledingham married in 1913 Barbara, daughter of David Fowler. They had two children, a son and a daughter, both of whom are following the discipline of medicine. His scientific attainments were of a high order; his life was dedicated to scientific research, and by precept and example he stimulated enthusiasm in others. His kindly and unassuming nature endeared him to colleagues and associates, and above all to those who were honoured by his personal friendship. R. ST. JOHN-BROOKS.

WE regret to announce the following deaths:

Prof. G. D. Birkhoff, Perkins professor of mathematics in Harvard University, on November 12, aged sixty.

Prof. D. M. Blair, regius professor of anatomy in the University of Glasgow, on November 10, aged forty-eight.

Prof. R. J. Rowlette, King's professor of materia medica and pharmacy in the School of Physic, Trinity College, Dublin, and president during 1940–43 of the Royal College of Physicians of Ireland, on October 13, aged seventy-one.

Prof. F. J. Wilson, Freeland professor of chemistry, Royal Technical College, Glasgow, on October 18, aged sixty-four.

# NEWS and VIEWS

## Royal Society: Royal Medals

H.M. THE KING has approved of the following awards of the Royal Society:

Royal Medal to Prof. D. Brunt, professor of meteorology at the Imperial College of Science and Technology, London, in recognition of his fundamental contributions to meteorology.

Royal Medal to Dr. C. R. Harington, director of the National Institute for Medical Research, in recognition of his work in the analysis and synthesis of thyroxine, and in immunological chemistry.

## Nobel Prizes for Physics for 1943 and 1944

THE Nobel Prizes for Physics for 1943 and 1944 have been awarded to Prof. Otto Stern, research professor in the Department of Physics at the Carnegie Institute of Technology, Pittsburgh, and Prof. I. I. Rabi, professor of physics in Columbia University, New York, respectively.

### Prof. Otto Stern

Stern has developed the method of molecular rays into a powerful tool for the investigation of the properties of ultimate particles. His first application was the experimental verification of Maxwell's law of velocity distribution in gases. Then followed his famous work, in collaboration with Gerlach, on the deflexion of atoms by the action of an inhomogeneous magnetic field on the atom's magnetic moment; this provided direct evidence for one of the strangest statements of quantum mechanics, the so-called quantization of direction. By an almost incredible refinement of this method, Stern succeeded in detecting and measuring the (about 2,000 times smaller) magnetic moments of some nuclei, the proton and the deuteron. It is this work for which he has now been awarded a Nobel Prize. But he used his method also for other purposes. He gave the most striking proof for the wave nature of ordinary matter, as formulated by de Broglie, in producing interferences by rays of ordinary matter, hydrogen and helium, reflected by crystal surfaces. Stern has also published important theoretical papers on thermodynamics and quantum theory. He was professor of physical chemistry at Hamburg, and when he was compelled to leave Germany in 1933 he became a member of the staff of the Carnegie Institute of Technology, Pittsburgh, Pennsylvania.

### Prof. I. I. Rabi

Rabi is an American who worked for some time with Stern in Hamburg and is now professor at Columbia University, New York. He developed the same ray method to a considerable precision for the measurement of the magnetic properties of atomic nuclei. His apparatus is based on the fact that one can produce ordinary electromagnetic oscillations of the same frequency as that of the Larmor precession of atomic systems in a magnetic field. By an ingenious application of the resonance principle he succeeded in detecting and measuring single states of rotation of atoms and molecules, and in determining the mechanical and magnetic moments of the nuclei. A Nobel Prize has been awarded to him for his great contribution to our knowledge of nuclear magnetism.

## Nobel Prize for Chemistry for 1943: Prof. G. C. von Hevesy, For.Mem.R.S.

PROF. G. VON HEVESY, of the University Institute for Theoretical Physics, Copenhagen, has been awarded the Nobel Prize for Chemistry for 1943. Prof. von Hevesy's earlier work was mainly in the field of radioactivity and radioactive isotopes. He determined the valency and electromotive series of the radio-elements, and established the identity of radium D with lead. Investigations on the 'self-diffusion' in liquids and solids introduced the use of radio-elements as indicators in following the movements of common elements with which they are isotopic, and this technique he has developed in chemistry, physics and biology, where the use of 'tracer elements', which now include artificial radio-elements, has become very important in the elucidation of reaction mechanisms, and in following the processes of metabolism. Prof. von Hevesy's most recent work is in this field. His work with Brönsted on the separation of isotopes of mercury and chlorine by diffusion has become classical.

In 1923 Coster and von Hevesy announced the discovery of a new element, which they named hafnium (after Copenhagen), in zirconium minerals (*Nature*, 111, 79; 1923). The discovery was made by the X-ray spectrum method, and in later publications the use of this method in quantitative chemical analysis was developed. The search for hafnium in various minerals led to a broader interest in the distribution of the elements in the inorganic and organic worlds, and in problems of geochemistry.

Radioactivity was enriched in some later work on the activity of potassium and samarium, and the detailed study of the radioactivity of the rare earths. Apart from the discovery of hafnium, Prof. von Hevesy is perhaps best known for his work in the field of general radioactivity (in which chemical methods and interests have predominated), and on radioactive indicators, but his researches have spread into many fields, all of which have been enriched by his discoveries.

The Nobel Prize for Chemistry for 1944 has been reserved.

## Vladimir Komarov, President of the U.S.S.R. Academy of Sciences

VLADIMIR KOMAROV, president of the Academy of Sciences of the U.S.S.R., celebrated his seventy-fifth birthday on October 14. It also marked the fiftieth anniversary of his scientific work. Komarov holds many posts; thus in addition to being president of the Academy of Sciences of the U.S.S.R., he is chairman of the Council for Studying the Production Potentialities of the U.S.S.R., chairman of the All-Union Botanical Society and the All-Russian Society for the Conservation of National Resources, head of the Department of Geography in the Botanical Institute of the Academy of Sciences, and head of the Botanical Department of the University of Leningrad. In addition, he is editor of leading Soviet periodicals on biology and author of more than two hundred published works, including a number of monographs, text-books and papers of botanical interest. Komarov has taken part in, organized and directed nine large research expeditions in Central Asia, the Far East and Kamchatka, and has become the leading authority on the flora of Asia and particularly of the Far East. More than sixty plant species have been named after him.

Komarov's first major work was a "Flora of Manchuria", published in three volumes during 1901–7. His second big work was "An Introduction to the Flora of China and of Mongolia", published in 1908; and his third great contribution to science is his "Flora of the Kamchatka Peninsula", which appeared in three volumes during 1927–30. Apart from these works, Komarov has published a description of his travels through Kamchatka, and a number of essays on the botany and geography of the Far East. The publication of the "Flora of the U.S.S.R." was begun in 1934 under Komarov's direct supervision. It runs into twenty or so volumes and contains a description of all plants known to exist on the territory of the U.S.S.R.

Komarov adds public activities to his scientific work. He is a deputy of the Supreme Soviet of the U.S.S.R. and a member of the Far East Territorial Executive Committee. During the German invasion, Komarov went to Sverdlovsk, where he organized the Commission for Mobilising the Resources of the Urals, Western Siberia and Kazakhstan for war needs. For its work the Commission was awarded the Stalin Prize in 1942. Komarov has been awarded the title of Hero of Socialist Labour, the Order of Lenin, and the Hammer and Sickle Gold Medal, for outstanding scientific work and his service in the organization of Soviet scientific institutions. The Academy of Sciences is to publish a biography and selected works of Komarov; it is also establishing in the Academy of Sciences an annual Komarov Prize of 20,000 roubles for the best work in botany, and eight Komarov fellowships in botany at the Universities of Leningrad and Moscow and the Botanical Institute of the Academy of Sciences. A children's home named after Komarov is to be opened in Moscow for children of scientific workers who perished at the front during the present War.

## Chair of Zoology at University College, Cardiff: Prof. James Brough

AT the opening of the present session, Prof. James Brough entered upon his new duties as professor of zoology and comparative anatomy in University College, Cardiff, a post upon which distinction had been conferred by the personality and prosperous tenure of the late Prof. W. M. Tattersall. The appointment is an interesting one, because Brough's honours degree, taken at Armstrong College, Newcastle upon Tyne, was in geology, and his published researches are almost entirely palæontological. But he has used his geological knowledge with the avowed and persistent aim of interpreting the evolutionary history of the bony fishes, and his researches have already thrown new light on that difficult problem and have proved to be of fundamental importance for the study of the Palæoniscids. To further these studies he has travelled far and wide, adding to his material by collecting in South Africa and Rhodesia, in the Austrian Alps, in northern Italy and in Spitsbergen, studying in London and Edinburgh, in Stockholm, Paris, Frankfort and Milan. His zoological knowledge, reinforced by his palæontology and his own vivid personality, gave verve and imagination to his teaching in the Department of Zoology in the University of Edinburgh, from which he proceeded to Cardiff, and in his earlier post in the University of Manchester. During the War, he has assisted the Ministry of Food by acting as insect infestation inspector for the south-east district of Scotland. Dr. Brough's interest in educational methods and his researches, with which must be linked the studies in the early history of the Amphibia so successfully followed by his wife (Dr. Margaret Steen), promise well for the continued prosperity of the Department of Zoology at Cardiff.

## Prof. Frank Goldby

PROF. FRANK GOLDBY, Elder professor of anatomy in the University of Adelaide, has been appointed to the chair of anatomy at St. Mary's Hospital Medical School, London. Goldby entered Caius College, Cambridge, as Tancred Student and Scholar in 1920 and obtained first-class honours in Part I and Part II (Anatomy) of the Natural Sciences Tripos. In 1923 he was awarded the Frank Smart Research Studentship and spent a further year in Cambridge working under the direction of Prof. J. T. Wilson. His clinical studies were pursued at King's College Hospital, London, where he came under the influence of Kinnier Wilson. He qualified M.R.C.S., L.R.C.P. in 1925, M.B., B.Ch. in 1927 and M.R.C.P. in 1928. During these years he held various residential appointments at his hospital, including the post of assistant pathologist.

In 1931, largely on the advice of Elliot Smith, Goldby became demonstrator of anatomy at University College, London, and in 1932 he went to Hong Kong as lecturer in charge of the Anatomy Department during the absence on leave of Prof. Shellshear. In 1933 he returned to Cambridge as demonstrator of anatomy, and, when Prof. H. A. Harris, of University College, London, succeeded Prof. J. T. Wilson in 1934, Goldby was promoted to a University lectureship in anatomy and was elected fellow and afterwards steward of Queens' College. In 1937, on the return of Prof. Wood Jones to Manchester, Goldby was elected to the Elder chair of anatomy in the University of Adelaide. Prof. Goldby's researches have been mainly in the field of neurology, and range from epibranchial placodes in the head region of the sparrow, over the cerebral hemispheres of the reptile to the visual pathway in mammals. In 1936 his thesis on "The Experimental Investigation of the Cerebral Hemispheres of Lacerta viridis" gained him the Cambridge M.D. and the Raymond Horton Smith Prize.

## Dr. Murray Macgregor

THE Clough Memorial Medal of the Edinburgh Geological Society for the years 1943–44 has been awarded to Dr. Murray Macgregor in recognition of his outstanding contributions to the geology of Scotland and in particular of the Scottish coalfields. During Dr. Macgregor's long service on the Geological Survey in Scotland, where he has been in charge since 1925, his main task as a worker and administrator has been connected with the geology of the Scottish coalfield area. In his extensive series of original contributions in this sphere, his presidential address to the Geological Society of Glasgow in 1927, entitled "Scottish Carboniferous Stratigraphy", was an outstanding work. Dr. Macgregor has achieved conspicuous success in organizing increasingly detailed work on Scottish mineral deposits and in promoting close collaboration with the mining and industrial community. He has thus been in a position to give authoritative advice to the Scottish Coalfield Committee, appointed by the Secretary of State for Scotland in 1942, and to make important contributions to this Committee's report, now in course of publication. Dr. Macgregor has also made valuable

contributions to the geology of the rocks of the Highlands and of the glacial deposits of central Scotland, and he played a big part in the preparation of the Scottish exhibits for the opening of the new Geological Museum in London in 1935.

## British Empire Cancer Campaign

At a recent meeting, the British Empire Cancer Campaign allocated a sum of £39,000 for the continuation of cancer research during the calendar year 1945. This sum compares with grants totalling nearly £36,000 for the present year. The principal grants are as follows: £10,613 to the Royal Cancer Hospital (Free), including the Chester Beatty Research Institute; £8,000 to the Middlesex Hospital; £3,500 to St. Bartholomew's Hospital; £1,800 to the London Hospital; £2,743 to Mount Vernon Hospital and the Radium Institute; £850 to St. Mark's Hospital, City Road; £1,100 to the Marie Curie Hospital; £120 to the Bristol University Cancer Research Committee; £2,300 to the Cambridge University Cancer Research Centre; £1,740 to the Oxford University Cancer Research Centre; £1,125 to Westminster Hospital; and £5,165 for the expenses of cancer research at the Glasgow Royal Cancer Hospital, University of Glasgow, Institute of Animal Genetics of the University of Edinburgh, University College, Nottingham and St. Thomas's Hospital. These grants are additional to independent expenditure on cancer research by the autonomous branches of the British Empire Cancer Campaign in Birmingham, Yorkshire, Lancashire, Cheshire, North Wales, Northumberland, Cumberland and Durham.

## Pest Control in French North Africa

A recent publication ("Les Nouvelles Méthodes Insecticides et Les Épidémies." By Dr. A. L. Lepigre. Centre Nationale de la Recherche Scientifique, Algiers) describes what is being done to reduce losses at the ports, in the marshalling yards and in the agricultural depots in French North Africa, resulting from infestation by insects and rats. The loss of potatoes caused by the tuber moth is stated to exceed 50 per cent within three months of harvesting, most of which loss is preventable by fumigation. Dr. A. L. Lepigre, whose pioneer work on the fumigants ethylene oxide and methyl bromide is well known, describes the fumigants and methods now in use in the eight large official stations for *désinsectisation* in Algiers, and the possibility of using vacuum and mobile chambers. Ethylene oxide, hydrogen cyanide and methyl bromide are recommended; but it seems that ethylene oxide is not available in Algiers at present. Chlorpicrin, once highly favoured by the French authorities, is described as being too unpleasant. A brief account of these fumigants is given, and special interest is attached to the statement that ethylene oxide is bactericidal as well as insecticidal, and as such is probably more effective than formalin or sulphur dioxide.

The need for specialists trained in fumigation practice is specially stressed. Loss of lives by typhus, and loss of foodstuffs and other commodities, still occur on a large scale, losses which can on Dr. Lepigre's showing be prevented if the organization of trained staff and equipment, which he describes, can be provided. That is true of many military and civilian bases and depots apart from the North African—in India for example—but there is little prospect of effective action until trained practitioners are available.

## British Rheologists' Club

The fourth annual general meeting of the British Rheologists' Club was held at the University, Reading, on Saturday, October 21. The retiring president, Commander C. F. Goodeve, took the chair at the business meeting. The following were elected officers for the ensuing year: *President*, Prof. E. N. da C. Andrade; *Hon. Secretary*, Dr. G. W. Scott-Blair; *Hon. Treasurer*, Dr. V. G. W. Harrison. The following were also elected to the Committee: Mr. R. L. Brown, Dr. C. A. Maunder Foster, Dr. E. W. J. Mardles, Dr. L. R. G. Treloar. Dr. Scott-Blair reported an increase of more than ninety in the membership figures during the past year. There had been three general meetings, of which one had taken the form of a week-end conference. This had led to closer co-operation between rheologists working in numerous fields. The Committee especially welcomed the newly established contacts with metallurgists. Very cordial relations existed with the (American) Society of Rheology, and it was hoped in the near future to make contact with Soviet rheologists through the courtesy of the Embassy of the U.S.S.R. The business meeting was followed by a discussion on "Tack" introduced by Dr. N. A. de Bruyne and Mr. R. F. Bowles.

## Dust Precipitation from Boiler Flue Gases

A paper on this subject was read in London on November 2 before the Institution of Electrical Engineers, by John Bruce. In it the author deals particularly with the electrostatic precipitation of dust entrained by flue gases produced from the combustion of anthracite in pulverized form. The paper describes field experiments and results on a pilot-scale electrostatic precipitator operating on such flue gases, as well as the salient features of a large-scale commercial installation. Some of the operating results obtained therefrom are also discussed.

## Announcements

Prof. M. N. Saha, of the University College of Science and Technology, Calcutta, will deliver a lecture before the Physical Society on "A Physical Theory of the Solar Corona" on November 23, at 5.0 p.m. The lecture will be given in the rooms of the Royal Society, Burlington House, Piccadilly, London, W.1, and members of the Royal Astronomical Society are also invited.

The Melbourne correspondent of *The Times* announces that Mr. W. Russell Grimwade, a member of the Council of the University of Melbourne, has given the University £A50,000 for the foundation of a school of biochemistry devoted both to teaching and research. Mr. Grimwade, who is chairman of the directors of Drug Houses (Australia), Ltd., manufacturing chemists and druggists, has been active in the war-time production in Australia of drugs previously imported.

From time to time correspondents have written offering to present unwanted issues of *Nature* to institutions or libraries. In view of the many losses sustained by French universities and libraries during the German occupation, and the difficulty in replacing such losses, readers may like to know that Prof. P. Auger, Commissariat de l'Education Nationale, 1 Carlton Gardens, London, S.W.1, is prepared to receive copies of *Nature* for dispatch to France.

## A Severity-Rate for Industrial Accidents and Sickness

THE effects of economic and social conditions upon absence from work initiated by sickness and injury are especially important at the moment in view of the changes in workmen's compensation arrangements proposed by the White Paper on Social Medicine and other similar publications.

All factories keep records of sickness and accident incidence, though they vary in detail. A factory showing a low rate of accident is not necessarily one where every possible safety measure is applied. A low accident-rate might equally well be due to inadequate facilities for reporting injury—an out-of-the-way first-aid room, an unsympathetic medical staff, or wage and compensation arrangements which make the workers fear loss of working time and so to carry on without reporting sickness or injury unless and until it proves serious. Such delayed reporting cases nearly always prove more serious than they would have had they received prompt medical attention.

These factors, which are external to purely industrial risk, considerably invalidate estimations based on the reported incidence of sickness or accidents. A secondary measure is required—a measure of the severity of reported cases. Severity, in this connexion, is best defined as the absence from work caused by sickness or injury.

Three main forms of severity estimation have been available for the preparation of accident statistics.

(1) 'Disabling accident' rate. Accidents which involve more than three days absence from work are reportable under the Workmen's Compensation Act and the Factory Acts. To this is often added a 'severe accident' rate, defined by the nature of injury. These are usually expressed as rates per 1,000 men (per year) or per 100,000 man-shifts.

(2) 'Lost time' records. Absence is recorded by an accountancy system in which cases still absent at the end of a records period are carried forward into the subsequent period. Thus the statistics are not completely related to any one records period. Arbitrary 'terminations' are introduced to avoid the cumulative effects of the very long term absences. Fatalities are considered separately.

(3) Estimation of lost time by the International Labour Office Severity Scale. This tabulates the average lost time caused by various injuries. It facilitates rapid preparation of statistics; but, by its nature, it is not susceptible to the effects of changes in economic or social conditions.

The following account briefly describes a new measure. It is approximate only, but further work is being carried out to diminish its error.

Given that the minimum delay in preparing sickness and accident statistics is desirable for practical purposes, an absolute measure is impossible. The aim, therefore, was to discover a theoretical distribution approximating to the actual distribution of absence, the constants of which could be calculated from incomplete data. The theoretical distribution chosen is that of the exponential law of decay. Its constants are (i) the origin, taken as the number of cases involving more than three days absence (conforming to the Workmen's Compensation and Factory Acts) and (ii) the logarithmic decrement, calculated from the origin and the number of cases involving more than thirty days absence. The thirty days specification is arbitrary, and is used so that the theoretical distribution can be calculated one month after the end of the records period. Thus each records period has self-contained statistics, and there is no need to take separate account of fatalities or cases of prolonged absence, although further work is required to make the extrapolated curve a more accurate estimate of these cases.

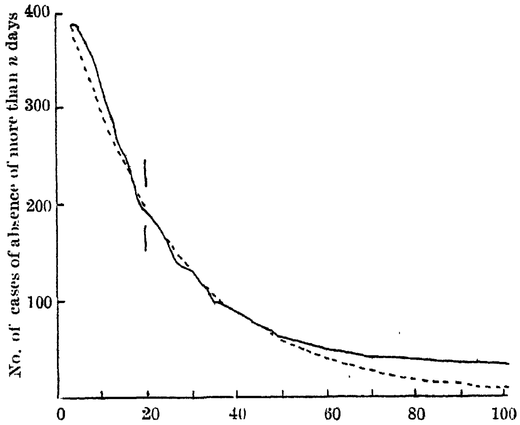

Fig. 1. DATA FOR 1938, 39, 40. FULL LINE, ACTUAL DATA; BROKEN LINE, THEORETICAL DISTRIBUTION. MEDIAN ABSENCE, 19·06 DAYS.

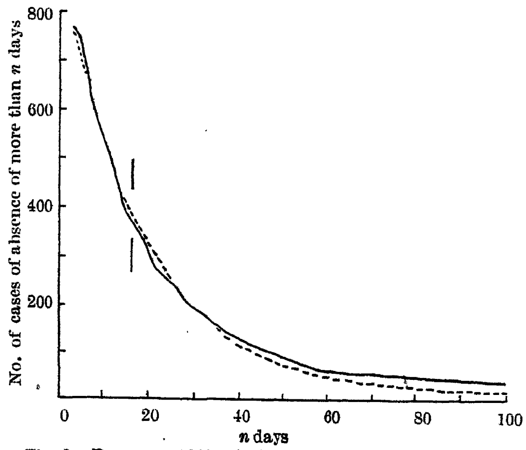

Fig. 2. DATA FOR 1941, 42, 43. FULL LINE, ACTUAL DATA; BROKEN LINE, THEORETICAL DISTRIBUTION. MEDIAN ABSENCE, 16·27 DAYS.

In the examples given (see accompanying graphs) number of cases of absence of more than $n$ days is plotted against $n$. The logarithmic decrement is calculated:

$$\text{Logarithmic decrement} = \frac{\log A_3 - \log A_{30}}{27},$$

where $A_3$ is the number of cases absent for more than 3 days and $A_{30}$ is the number of cases absent for more than 30 days.

The theoretical distribution is calculated:

Expected $A_n = \frac{A_3}{e^{x(n-3)}}$, where $x.\log e$ is the logarithmic decrement.

It is convenient to transform the logarithmic decrement into the half-period of decay. This gives the median absence:

$$\text{Median absence} = \frac{0{\cdot}3010}{\text{log decrement}} + 3 \text{ days.}$$

The graphs show the method demonstrating a change in severity during the war years. Data are from one firm which has not changed its processes during this period, nor has there been any major change in the quality of labour employed. The disabling accident rate for 1938, 1939, 1940 is 86 per 100,000 man-shifts, and for 1941, 1942, 1943 it is 118 per 100,000 man-shifts. By themselves these figures suggest a large increase in risk during the later war years. Absence medians show a decrease in severity of reported accidents during the latter period (medians at 19·96 and 16·27 days for the two periods). Thus the increase in accident-rate can be attributed in part to increased willingness to report injury and to take immediate absence of short duration. The main social and economic changes likely to have caused this increased willingness to report and be absent are higher wages, more secure employment, revised compensation arrangements and regulations against absenteeism.

If we consider each year separately

| Year | Rate per 100,000 man-shifts | Median absence |
|---|---|---|
| 1938 | 90 | 21·9 |
| 1939 | 94 | 17·7 |
| 1940 | 78 | 20·5 |
| 1941 | 105 | 17·7 |
| 1942 | 119 | 15·4 |
| 1 43 | 131 | 16·8 |

These show the general trend of increase in accident-rate and decrease in severity during the war years. The exception noted for 1940 is presumably to be explained by the overriding pressure of work in the summer and autumn of that year, when the workers realized the urgent need of supplies and considered personal injury of minor importance.

Similar treatment of data from other sources shows a difference in severity of accidents reported by full-time workers and by part-time workers.

The conclusion is that reporting of sickness and injury in industry may be affected by factors unrelated to industrial risk. Comparative work must consider the severity of the reported cases. The median absence, obtained by the method described above, is recommended as a measure of severity.

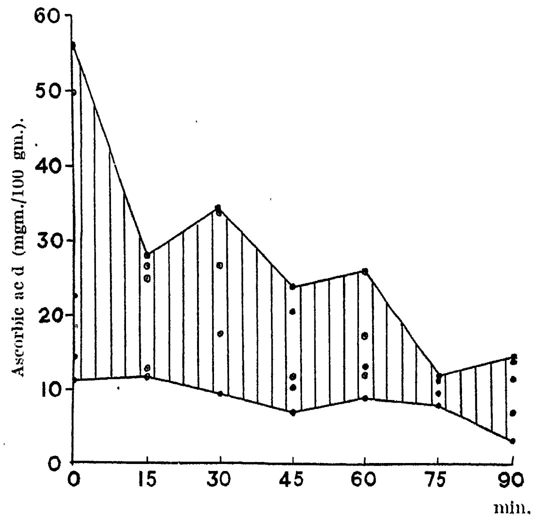
## Sampling of Cooked Cabbage in Nutrition Surveys

IN the course of an investigation which we carried out at a local hospital during the winter, it became necessary to estimate the loss of ascorbic acid which occurred in cabbage in the interval between the completion of cooking and consumption in the wards and dining-rooms. This interval was usually between thirty minutes and one hour, during which time the cabbage was kept in water-jacketed boxes at 60–70° C. We failed to obtain satisfactory duplicate analyses of samples taken in the hospital, and it was therefore decided to carry out experiments under similar conditions in the laboratory.



Cabbage was cooked, strained and kept at 60–70° C., samples being taken at intervals. The ascorbic acid content was estimated by titration with 2 : 6 dichlorophenol-indophenol, using a sulphuric acid/metaphosphoric acid solution for stabilizing the vitamin between sampling and estimation. It was again not found possible to obtain agreement between either duplicate or triplicate samples. Reference to the literature in which satisfactory analyses are given[1] revealed the fact that the cabbage used was either minced or finely chopped. We can confirm that there is no difficulty in obtaining good agreement between replicate samples of cabbage under these conditions. But a difficulty arises when it is not possible to use methods for homogenizing the cabbage, as in field work, where samples taken for analysis are usually those actually put out on to plates during the service of the meal. The results given in the papers referred to above apply only to ideal conditions which are rarely encountered in work of this sort.

An example of our results is given in the accompanying graph, which shows an attempt to construct a curve recording the loss of ascorbic acid on keeping cabbage hot. Five samples were taken at each time interval. An even wider variation in values was obtained when ten samples were taken; for example, 32–75 mgm.; 25–78 mgm. and 11–56 mgm. per 100 gm. cabbage. Some of these values are as much as $\pm$ 70 per cent from the mean. Care was taken that the samples analysed did not consist almost entirely of stalk or of leaf.

The experiments suggest that in field work, where an attempt is made to assess the ascorbic acid content of food actually consumed, it is not possible to obtain trustworthy results unless the food is normally mashed or minced before serving.

## Distribution of Antithyroid Activity in Tissues

CONTINUING our investigation of the antithyroid function of paraxanthine and related compounds[1], we have carried out estimations of the antithyroid activity in mammalian tissues and blood.

All the extracts were made by methods similar to that described in our previous letter except that the purification was not carried beyond the mercury precipitate. The extracts at this stage contain other substances besides paraxanthine and it is possible that some of these are active. We have indeed evidence that suggests that the active substance in thyroid extracts is not identical with paraxanthine, though it appears to be related to it and may perhaps be formed from it in the body. Work on the identification of this substance is being continued.

In these circumstances we do not wish to contend that the active substance in any of the organs or fluids is paraxanthine, except that in liver, from which (as from urine[1]) paraxanthine has been isolated. It is, however, convenient to report the results in terms of paraxanthine, that is, as the concentrations of paraxanthine that would give the activities present in the extracts, and this we have done.

The true tissue contents will be higher than are given here owing to loss during the extraction. But since the process of extraction was similar for all the extracts, it is probable that the losses were of the same order in them all.

Antithyroid activity was estimated by the method described in the previous letter, in which use is made of the change of form of the temperature/heart-rate curve of the frog's heart. We have checked the accuracy of this method by estimating the paraxanthine in three solutions the strengths of which we did not know at the time of estimation. Our results were within 10 per cent of the true concentrations. We think that 20 per cent is the largest error that is likely to occur in the estimations. This error would not include losses during extraction.

Our results are given in the accompanying table. Each figure gives the result of extractions from a single sample of tissue, except the figures for liver which give the range of ten extractions.

| Tissue | Source | Content $\mu$ gm. per gm. (wet weight) |
|---|---|---|
| Skeletal muscle | Cattle | 1·2 |
| Heart muscle | Cattle | 2 |
| Small intestine | Pig | 1·7 |
| Lung | Cattle | 1·4 |
| Liver | Cattle | 0·2–0·9 |
| Ovary | Cattle | 8 |
| Testis (immature) | Pig | 4 |
| Brain | Cattle | 5 |
| Spleen | Cattle | 10 |
| Thymus | Cattle | 8 |
| Pituitary | Cattle | 8 |
| Pancreas | Cattle | 6 |
| Thyroid | Cattle | 500, 600, 750, 470. |
| Thyroid | Human (normal)* | 600, 1,400, 750, 1,000, 833, 666, 700, 800, 830, 850, 770, 950. |
| Thyroid | Human (thyrotoxic)* | 245, 133, 165, 105. |
| Thyroid | Human (adenoma)* | 1,100, 1,100, 1,250. |
| Whole blood | Cattle | 0·4 (per c.c.) |
| Whole blood | Pig | 0·15 ,, ,, |
| Blood cells | Cattle** | 0·0059 ,, ,, |
| Plasma | Cattle** | 0·176 ,, ,, |

* We are greatly indebted to Prof. H. M. Turnbull, of London Hospital, for these samples.

** From the same sample of blood. Content of the whole blood of this sample 0·132 $\mu$gm. per c.c.

The most striking features of these results are: (1) the very high activity of the extracts of thyroid tissue—on the average an extract of normal thyroid is 400–500 times as active as extracts of tissues such as muscle, intestine and lung; and (2) the wide variation of the activity of the thyroid extracts with the condition of the gland. In general, the concentration of antithyroid activity in the tissues runs parallel with the amount of iodine they contain. This is so in the thyroid as compared with other tissues, and it is also shown in the slightly higher contents of glandular tissues as compared with non-glandular[2]. Our thyrotoxic thyroids came from patients which had been treated with iodine before extraction of the gland; they would have contained as much iodine as normal thyroids[2]. It is of interest to find that the antithyroid contents of thyrotoxic thyroids are relatively low even after treatment with iodine.

## Anti-sulphanilamide Activity of 2-Aminopyrimidine-5-carboxylic Acid

THE observation of Woods[1], that the anti-bacterial activity of sulphanilamide is inhibited by *p*-aminobenzoic acid, has been followed from time to time by observations recording a similar anti-sulphanilamide action for other compounds chemically unrelated to *p*-aminobenzoic acid. Thus Harris and Kohn[2] have shown that *dl*-methionine antagonizes sulphanilamide action. Martin and Fisher[3] have reported that adenine possesses anti-sulphanilamide activity in mice infected with streptococci comparable with that possessed by *p*-aminobenzoic acid. Snell and Mitchell[4] found that adenine, guanine, xanthine and hypoxanthine, as well as *dl*-methionine, reversed sulphanilamide bacteriostasis of certain lactic acid bacteria, although the results were largely dependent on the particular organism and conditions employed. Anti-sulphanilamide action has also been demonstrated with urethane[5].

In the course of biological examination of some pyrimidines, we have recently examined 2-aminopyrimidine-5-carboxylic acid[6]—an acid bearing a close structural relationship to *p*-aminobenzoic acid. It displayed no anti-bacterial action against *Streptococcus pyogenes in vitro*, but possessed distinct sulphanilamide inhibitory powers, although in smaller degree than *p*-aminobenzoic acid. Thus *p*-aminobenzoic acid was found to be 2,000 times as effective as 2-aminopyrimidine-5-carboxylic acid in inhibiting sulphanilamide bacteriostasis of *Streptococcus pyogenes in vitro*.

## Preparation of Cell-free Plasma Coagulase of *Staphylococcus aureus*

IN 1908, Much reported that certain strains of *Staphylococcus* had the property of coagulating oxalated or citrated human blood plasma. This is nowadays considered as one of the most characteristic features of pathogenic *Staphylococcus aureus*, and is used to differentiate it from various other cocci. To my knowledge, attempts to separate the plasma coagulase from the bacterial cells have so far failed; for example, in personal experiments by filtration of broth cultures through Seitz and Chamberland filters, separation of cells by the centrifuge, killing the staphylococci by heat or the vapour of ether or chloroform.

In order to explain the inactivity of the filtrate or centrifugate, it has been taken as a working hypothesis that coagulase is not produced in such cultures, but is formed only in presence of plasma. This also had another basis in my finding that the rate of coagulation was independent of the age of broth cultures and was uninfluenced by repeated washing of the suspensions. Such results were opposed to the existence of preformed coagulase in cultures on ordinary media.

To verify the hypothesis that coagulase is produced only in contact with plasma, 10–25 per cent of human citrated plasma was added to a series of flasks containing nutrient broth. Control sets contained broth, and broth with sodium citrate only. All were inoculated with *Staphylococcus aureus*, three separate strains being tested. After twelve hours incubation at 37° C., the cultures were centrifuged and the supernatant fluid filtered through Chamberland *L*3 filters. The filtrates, which were tested for sterility, were added in various amounts to separate 1 c.c.'s of concentrations of human citrated plasma ranging from full strength to 1 : 40 in 0·85 per cent sodium chloride solution. While filtrates of broth and broth *plus* citrate were inactive, the filtrates of plasma-broth cultures showed a very strong coagulating power; for example, one drop of 1 : 10 dilution coagulated concentrated plasma in two hours and 1 : 10 plasma in fifteen minutes. Thus it appears that cell-free plasma coagulase can be obtained when *Staphylococcus aureus* is grown in presence of human plasma.

There is also abundant production *in vivo* by *Staphylococcus aureus* of plasma coagulase, which can be demonstrated readily in pus, etc. This 'direct coagulase test', which will be described elsewhere, affords a very rapid and reliable method of detecting staphylococcal infections.

After the above letter was written, my attention was directed to a paper by W. Smith and J. H. Hale[1], who found that by means of 'Gradocol' membranes coagulase could be demonstrated in broth culture filtrates. It is of interest that, as I observed, the addition of plasma to a broth culture led to the appearance of coagulase which was easily filterable through filters of the Chamberland type, whereas in absence of plasma neither centrifugates nor filtrates were active.

## *Ailanthus*, Source of a Peculiar London Honey

THERE can be few beekeepers in the heart of London, and one would not expect the Metropolitan area to be a promising locality for honey production. I therefore welcomed an opportunity of examining a sample of honey from an apiary in Kensington not far from Kensington Gardens, which was brought to my notice in 1943, on account of its unusual flavour. This honey was of a pale greenish-brown colour and after about three months in store set with a fine granulation. The first impression on tasting it was of a mild floral bouquet, but this was followed by a persistent after-taste reminiscent of cats. This flavour recalls exactly the cat-like odour given off by elder flowers (*Sambucus nigra*) when they are drying, and at first suggested that elder might be responsible. The pollens obtained by dilution in water and sedimentation were examined, but *Sambucus* pollen was absent. The most abundant, forming 44 per cent of the total, came from the Tree of Heaven, *Ailanthus altissima*, which is common as a street tree in Kensington. This species is diœcious, and the male flowers, especially, have a strong rather unpleasant odour recalling that of elder. A second major constituent was the sweet chestnut, *Castanea sativa*, the flowers of which also have a strong unpleasant aroma.

The fact that the peculiar after-taste is attributable to the *Ailanthus* was confirmed by the examination of a 1944 honey sample from the same apiary. In this (see table) *Ailanthus* pollen again preponderates, but *Castanea* forms rather less than 4 per cent of the total. The other major constituent in this season was privet, *Ligustrum vulgare*, which yields a coarse-flavoured honey, but this is of not uncommon occurrence and it is not responsible for the after-flavour.

POLLEN ANALYSES OF KENSINGTON HONEYS. THE FREQUENCY OF THE MAIN CONSTITUENTS IS EXPRESSED AS A PERCENTAGE OF THE TOTAL NUMBER OF POLLEN GRAINS.

| Pollen type | Season | |
|---|---|---|
| | 1943 | 1944 |
| Tree of Heaven, *Ailanthus altissima* | 44·0 | 37·7 |
| Sweet chestnut, *Castanea sativa* | 26·0 | 3·7 |
| Privet, *Ligustrum vulgare* | 6·2 | 28·8 |
| Limes, *Tilia* spp. | 6·6 | 4·0 |
| Willow herb, *Epilobium angustifolium* | 0·6 | 8·8 |
| Horse chestnut, *Aesculus Hippocastanum* | 0·6 | 1·7 |
| Miscellaneous pollens | 16·0 | 15·3 |
| | 100·0 | 100·0 |

Beekeepers are apt to attribute unpleasant flavours of unknown origin to the presence of honeydew in the honey. Off flavours from this cause are due not to the honeydew itself but to the sooty moulds that grow in it. Several fungi are concerned, probably the most abundant in Great Britain being *Cladosporium herbarum*. On the evidence of the sooty mould spores, there was very little honeydew in the honeys under review, the mould spores being 5·0 and 9·1 per cent as numerous as the pollen grains in 1943 and 1944 respectively.

The cat-like odour of elder flowers is lost when they are quite dry, and gives way to a pleasant aroma. In addition to medicinal and cosmetic uses, the flowers have been employed in food products to impart a muscatel flavour. The substances responsible for this flavour presumably are derived from the unpleasant smelling constituents of the essential oil. The nature

of the changes taking place in the oil is not mentioned in the literature, though oxidative changes may be involved. Bearing this in mind, the 1943 honey was tasted from time to time, and it was found that the cat-like flavour gradually faded and gave way to a muscatel flavour of increasing intensity. By July 1944, the cat-like flavour had disappeared entirely, leaving a delicious rich muscatel flavour. Honey is usually eaten within a short period of its production, but as with wines and cheeses it would pay to store some kinds until the flavour matures. This applies to *Ailanthus* and *Castanea* honeys, the latter also losing its strong flavour on keeping, and possibly other ill-flavoured honeys that a beekeeper would feed back to his bees in disgust.

*Ailanthus* honey does not appear to have been recorded hitherto from Great Britain, although it has been reported from time to time from other countries. Zander[1], for example, mentions a sample which he describes as having a strong peculiar flavour recalling muscatel; evidently this was not fully matured. I am indebted to Mr. A. Chesnikov for the honey samples.

## Larval Growth-Stages of *Agriotes sputator*

THE analysis of wireworm populations has been impeded by lack of knowledge of the number of growth-stages through which wireworms pass during their larval life. In the course of a study of wireworm larvæ, I have found that the growth-stage to which any larva belongs can be determined by counting the number of teeth on the borders of the spiracles.

There are eight growth-stages, and the average number of teeth per row for each stage is as follows: on the thoracic spiracles, I, 3–4; II, 4·5–6; III, 6·75–9·75; IV, 10·5–14·25; V, 15·25–20·75; VI, 21·5–30·5; VII, 32·5–40·5; VIII, 42–62; and, on the abdominal spiracles, I, 0·25–2; II, 2·75–4; III, 4·5–6; IV, 6·75–9·25; V, 9·75–13·75; VI, 14–19·5; VII, 20–28·5; VIII, 29·25–39. All the spiracles of 950 larvæ have been examined, and all the larvæ, although collected at different times of the year, fall into these eight groups.

To count the teeth on all the spiracles is too laborious a process for large-scale work, and a method has therefore been devised whereby the growth-stage can be ascertained by examining a minimum number of spiracles while maintaining an accuracy of more than 97 per cent. The quick method is as follows. Count the teeth on the two outer rows of either thoracic spiracle. If the average number per row falls within the ranges of the eight groups given in column 1 of the accompanying table, the growth-stage is determined as indicated. If it does not, count the teeth on the other thoracic spiracle and test the average number of all four rows now counted against the groups in column 2. If the growth-stage remains still uncertain, recourse must be had to the abdominal spiracles, the teeth on one, two or three of which can be counted and tested similarly against columns 3, 4 and 5 of the table. If desirable, the teeth on any abdominal spiracles can be counted first, and columns 3, 4 and 5 consulted. Should this not show to which growth-stage the larva belongs, the thoracic spiracles should then be examined. By this quick method, all the larvæ can be placed in their growth-stages by counting the teeth on no more than five spiracles.

A full account of the investigation is being prepared for publication.

## Reduction by Carbon Dioxide of Susceptibility of Beans to Tobacco Necrosis Viruses

A COMPLICATING factor in the use of the local-lesion technique for estimating the concentration of plant viruses is that a standard inoculum may give widely different numbers of lesions on different leaves. Differences in age of the plant, nutrition, illumination and position of the leaf on the plant can all affect the susceptibility; but it is unknown whether they do so by altering resistance to injury during inoculation, or whether they produce more fundamental changes in the physiology of the injured cells which prevent infection. We have found that exposing plants to atmospheres containing 30–60 per cent carbon dioxide greatly reduces the susceptibility of bean plants (*Phaseolus vulgaris*, var. Canadian Wonder) to tobacco necrosis viruses. As this reduction can be brought about by exposure after inoculation, the effect is presumably due to physiological changes within the cell and not to the number of entry points opened during the inoculation.

The reduction in the number of local lesions depends on the length of exposure to carbon dioxide. To quote one experiment: plants exposed immediately after inoculation for 15, 30, 60 and 120 minutes gave 46, 39, 17 and 13 per cent of the number of local lesions produced on control plants. When plants are exposed for two hours to the gas mixture, they show the same reduced susceptibility whether inoculated with the virus immediately

before or immediately after exposure. The changes responsible for the fall in susceptibility are readily reversed on returning the plants to air, and four hours after exposure to carbon dioxide the treated plants are again as susceptible as untreated controls. Also, plants inoculated for four hours before exposure to carbon dioxide produce as many lesions as control plants.

The effect is unlikely to be a direct inactivation of the viruses, for they are unaffected by long exposure to saturated solutions of carbon dioxide. As exposure is ineffectual four hours after inoculation, it seems that within this time the virus is normally established in tissues where it multiplies, and that some changes in the metabolism of the cell prevent this establishment in the treated plants. Longer exposures than two hours could not be tried as they damaged the plants: even exposure for two hours causes obvious damage unless exposure is made below 10° C. We were, therefore, unable to see if carbon dioxide reversibly inhibits the multiplication of these viruses after they are established, as Woods[1,2] claims that treating plants with potassium cyanide reversibly inhibits the multiplication of tobacco mosaic and tobacco ringspot viruses. Woods attributes this effect to a reversible change in the respiratory system; as carbon dioxide can also reversibly affect respiratory systems of plants, the two phenomena may be related.

## *Alternaria Solani* on Tomato

THIS fungus, causing the well-known 'early blight' of potatoes and tomatoes in some countries, has not hitherto been found attacking tomato plants in Britain. There are, however, a few early records, none relating to serious outbreaks, which unfortunately were accompanied by incomplete and inadequate descriptions or by none at all and which, in the light of more recent knowledge of the species, are open to doubt.

In September 1944, in outdoor plantations in Kent and Sussex, this disease was found causing severe leaf and stem spotting to such a degree that, in one instance, a plantation of 1½ acres assumed a withered or 'scorched' appearance. Lesions occurred at the calyx end of the fruits, which started to rot and fall to the ground.

The fungus associated with the disease may be referred to *Alternaria Solani*, and all the symptoms induced on tomato agree fully with those described in other countries.

It has been thought advisable to make this preliminary announcement before the tomato crop of the 1944 season in Britain has been finally dealt with. A paper describing the occurrence in detail has been prepared for publication.

## Electron Mobility in Large Molecules

IN an earlier paper[1], I discussed the longitudinal and transverse polarizabilities of a number of bonds, as calculated from data on refractivity, Kerr constant and depolarization factor. The C–C single bond was exceptional in having a very high ratio (*c.* 100 : 1) of the longitudinal to the transverse polarizability. This indicates that in this bond the electrons can be displaced much more readily in a direction parallel to the bond than in a direction at right angles. It was suggested that this factor might be of importance in connexion with the structure of long-chain compounds.

It appears now that a number of measurable physical properties—polarizability, charge transfer spectra, colour, fluorescence, electrical conductivity and the Van der Waals' forces—are all closely related and may be of great significance with regard to the chemical and biological properties of large organic molecules.

In a series of papers[2], Mulliken has discussed charge transfer spectra and the effects of hyperconjugation. As the name implies, the charge transfer spectrum arises from transitions from an excited state which has an ionic wave function corresponding to the displacement of electrons within the molecule. The more highly conjugated and the more elongated is the structure, the nearer are the normal and the excited states, and the further the spectrum is pushed towards the visible. There is a corresponding enhancement of refractivity and, if the transitions in question are sufficiently intense, colour may also arise. These properties are particularly well exemplified among the polyenes, and Mulliken has suggested that they are related to the tendency of these molecules to polymerize. In β-carotene, his calculations indicate that an electronic charge oscillates over about 32 per cent of the length of the system of eleven conjugated double bonds.

In his theory of the dispersion forces, London[3] has shown the connexion between polarizability and the Van der Waals' forces. In a later paper[4], he has used my anisotropic bond polarizabilities and has also considered the forces between large molecules containing extended electronic oscillators. These forces ('monopole forces') are highly specific and no longer additive. Their range extends far beyond that of the ordinary Van der Waals' forces of small molecules, and this may be of significance in connexion with rubber-like elasticity and the aggregation of polymeric molecules into fibres. The forces are particularly strong in the case of conjugated systems, where the electronic oscillators are of considerable length and of relatively low frequency. Moreover, with regard to electrical conductivity, such a system "... forms something like a miniature piece of metal ...".

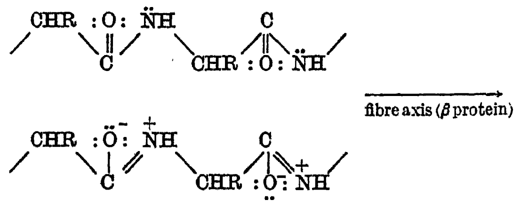
The connexion between polarizability and electrical conductivity had also been noticed by Herzfeld[5]. Among the elements, electrical conductivity is attained when the polarizability, as measured by the refractive index, reaches a critical value equal to the cube of the atomic radius. Weiss[6] has discussed fluorescence and the approach to metallic properties[7] among highly conjugated and carcinogenic hydrocarbons. In graphite, the conjugation reaches a very high level: there is appreciable conductivity, and metal-like salts can be obtained. In these, the anions

(for example, $HSO_4^-$, $ClO_4^-$) lie between the lattice planes of the graphite.

The high electron mobility in conjugated systems, arising from the delocalized $\pi$ orbitals, thus gives rise to very distinctive properties. Moreover, Mulliken has shown that a certain degree of conjugation ('third order' conjugation or 'hyperconjugation') exists even in fully saturated organic molecules. Hyperconjugation is a delocalization effect whereby C–H bonds tend to donate electrons to C–C and other bonds, and this is found to be a stabilizing influence in all organic molecules. It would appear, therefore, that there is an incipient injection of electrons into the chain and a certain degree of longitudinal electron mobility (quasi-conductivity) in any organic system. This effect is much increased whenever multiple bonds are also present. In this connexion, Bateman and Jeffrey[7] have recently observed a significant degree of bond shortening (to 1·43 A.) in the central bond of a 1 : 5 diene (geranylamine hydrochloride).

Mulliken has suggested that C=O groups can give rise to a very energetic type of hyperconjugation. Shortening has been observed in the C–C bonds in $CH_3.CHO$ (to 1·50 A.)[8] and in oxalic acid (to 1·43 A.)[9].

A system of this type is the polypeptide grid of the proteins in which the C=O bonds are in the 1 : 5 position to each other. Two alternative formal bond structures can be written as follows (see also Huggins[10]).



This system would be expected to have an appreciable electron mobility over the full length of the molecule and along the axis of the protein fibre. This may be of importance in connexion with the activity of nerve and muscle. By contrast, the fibres of plants, in which there is no nervous system of the type existing in animals, is based on cellulose. In this substance, opportunities for conjugation are much smaller than in protein. Cellulose fibres would thus be expected to show a lower electrical and optical activity and a higher chemical stability than corresponding fibres based on protein.

## Red Stannous Oxide

A CENTURY ago, Fremy[1] and Roth[2] described the preparation and properties of red forms of stannous oxide. More recently, Bury and Partington[3] and Weiser and Milligan[4] were unable to obtain these. The matter seemed worth investigating again in the light of a paper by Ehret and Greenstone[5] on red zinc oxide.

In work still in progress, it has been found possible to obtain products in all respects identical with those described by Fremy and by Roth, though by slightly different experimental procedures.

Fremy's method of preparation was modified by precipitating a solution of stannous chloride, containing hydrochloric acid, with excess of aqueous ammonia, heating the resulting thick suspension of stannous hydroxide for some time on the water bath, and finally evaporating thin, even films of the suspension to dryness in large porcelain dishes. After repeatedly decanting with boiled distilled water, and drying in vacuum, a deep orange powder is obtained.

Roth's oxide was obtained by heating a suspension of stannous hydroxide in very dilute acetic acid in presence of sodium hypophosphite. The product is deep crimson and of larger grain size than that obtained by Fremy's method.

The presence of free tin in the red oxides could not be established by amalgamation or by conductivity measurements. X-ray diffraction powder photographs taken with cobalt $K\alpha$ radiation showed the patterns from the two red oxides to be identical, but different from those of normal tetragonal stannous oxide and of stannous hydroxide.

The red stannous oxide appears, therefore, to be a distinct crystalline modification.

## Mr. F. Lincoln and the Cavendish Laboratory

MR. F. LINCOLN, who has been on the staff of the Cavendish Laboratory for fifty-four years and has been laboratory steward since 1902, retired on September 30. Generations of research students have passed through the Laboratory during the years of Lincoln's reign, and he is widely known to physicists throughout the British Empire and in other countries.

We are making him a presentation to mark our gratitude for his long and devoted service to the Laboratory, and I have written to past and present Cavendish men inviting subscriptions. There must, however, be many whom I have not been able to reach by a letter, and I would be glad to receive contributions from readers of *Nature* who wish to be associated with this gift to Mr. Lincoln.

W. L. BRAGG.

Cavendish Laboratory,
Cambridge.

# SUITABILITY OF A COOL MARITIME CLIMATE FOR SEED POTATO PRODUCTION

By DR. J. E. VAN DER PLANK
Department of Agriculture and Forestry, Pretoria

DURING a survey of the South African coastal areas, a test was devised for deciding if the climate of a maritime area was suitable for growing seed potatoes. It needs only the simplest apparatus, and has both practical and theoretical advantages over the current method of aphid surveys, which it might well supplement or replace.

In the seed potato areas of maritime climates—and we are concerned here with no other—freedom from the aphids which spread virus diseases depends, Davies[1,2] showed, on conditions which check their flight. These conditions are low temperature, high relative humidity, and wind. Wind will be considered later. The temperatures and humidities which are specially relevant are those during the warmest part of the day when aphids most readily take to the wing. Suitable limits of temperature are determined fairly easily. Actual reference to good seed areas suggests that the average daily maximum temperature for June, when migration normally occurs from winter hosts to potatoes, should not greatly exceed, and should preferably be somewhat less than, 65° F. It is the factor of relative humidity which has been the stumbling block. Records at the warmest part of the day are often not available. Davies[3] resorted to records for 9 a.m. in his survey of the Scottish areas. This is unfortunate. It implies without warrant a small rise in temperature during the day, for it is only in climates with small daily ranges of temperature that one can rely upon high relative humidities in the morning persisting for the rest of the day.

Paradoxically, one may dispense altogether with records of relative humidity as a measure of the humidity factor, and concentrate solely on the need for a small daily range of temperature. A small range ensures not only that the drop in relative humidity during the day is small, but also that the level of humidity is high, in the sense that small daily ranges are characteristic of climates in which moisture is abundant enough greatly to restrict the daily change of temperature by radiation. The relation between the relative humidity at the warmest time of the day and the daily range of temperature depends largely on latitude, season and climate; but our problem can be simplified by restricting it to finding what is a suitable daily range in a zone between fairly narrow limits of latitude, during a single month, June (or December in the southern hemisphere), in a cool maritime climate in which the mean maximum temperature for this month is about 65° F. or somewhat less. We can do this empirically, by referring to successful seed areas. The evidence which follows is that the daily range for June (measured as the difference between the mean maximum and mean minimum temperatures for the month) should be less than about 13° F. for a good area; that a range of 16° F. or more indicates unsuitability for seed; and that between these limits lie doubtful cases and, probably, cases in which the established meteorological stations are not exactly representative of the potato fields in the district.

In the western counties of Eire, where the dangerous aphid, *Myzus persicæ*, is extremely rare on potatoes[4], the daily range averages 11·4° F.[5]. In Scotland the areas found by Davies[3] to be nearly free from *M. persicæ* have an average range of 12·9° F. (Montrose, 13·7° F.; Banff, 11·6° F.; and Fortrose, 13·4° F.), while in the poor seed areas the average is 16·2° F. (Dundee, 16·9° F.; Edinburgh, 13·4° F.; Perth, 18·3° F.; and Cupar, 16·3° F.). In North Wales the range is 8·1° F. at Holyhead (Anglesey), where *M. persicæ* has been consistently scarce[6,7]; 13·1° F. at Aber (North Caernarvonshire), a 'moderately' good area[7]; and 16·5° F. at Sealand (Flintshire), a poor area for seed[1]. In Cornwall and Devon, to judge by the scant number of meteorological stations in the official list[5], the areas chosen by Staniland[8] for seed have a range of about 10·9° F. (Ilfracombe, 10·6° F.; Woolacombe, 10·0° F.; Bude, 12·8° F.; Newquay, 10·2° F.). Many areas were rejected by Staniland for reasons irrelevant to this discussion (presence of eelworm, proximity to market gardens, etc.); taken on the whole, *M. persicæ* is scarce over most of Cornwall, and the daily range is small, averaging 12·2° F. for the seven stations in the official list. By contrast, to give on a large scale an example of an area where *M. persicæ* is generally abundant in potato fields, the daily range at thirty-four stations in the English Midlands varies from 15·0° F. to 19·8° F., with an average of 17·6° F.; and similar high ranges are usual in all English and Welsh counties which, in Samuel's map, are shown to get more than 25 per cent of their seed from Scotland or Ireland. Finally, to take an example from the relatively small part of the United States with a cool maritime climate, Eureka, on the Californian coast, is a good seed area (M. R. Harris *in litt.*), and has a daily range of 9·2° F.

The criteria we have adopted—a mean maximum temperature about 65° F., or less, and a daily range of 13° F., or less, during June—are for readings taken in a Stevenson screen at the usual height above short grass. In applying the test to any site one is ultimately concerned with averages over many years, but in practice substantial accuracy may be possible in a single season by determining from old-established meteorological stations in the neighbourhood what correction must be made for seasonal abnormality.

Because it uses only a maximum and minimum thermometer and a Stevenson screen and because of the ease of taking readings, which any intelligent farmer could do, the test meets the need for surveys in enough detail to take into account local physical features (particularly aspect, altitude, and exposure to sea-winds) which greatly affect climatic suitability for seed production; and one hopes that the end of the War will see the release of enough meteorological apparatus to allow surveys to be started without delay. Existing records tell in broad outline what land is worth surveying. In South Africa, for example, a really suitable maritime climate is limited to a narrow barren strip along the west coast. In England and Wales sites with daily ranges not greater than 13° F., and mean maximum temperatures not above 65° F. during June are most likely to be found in the Isle of Man; Anglesey; Caernarvonshire; the western half of Merionethshire, Cardiganshire, and Carmarthenshire; Pembrokeshire; the western tip of Glamorganshire; Devonshire, especially the north to a depth of about fifteen miles from the coast, and to a lesser extent the south coast; Cornwall; the coast of Dorsetshire; and areas of varying depth along the

south and east coast from Hampshire (especially the Isle of Wight) to Norfolk. Whether conditions other than climate are suitable in these areas is beside our point.

Temperatures during June do not adequately explain variations in the prevalence of *M. persicæ* from year to year. These variations are closely linked with conditions during winter[7,10]. Thus, in Cornwall and Devon the very hard winter of 1939–40 greatly reduced the numbers of *M. persicæ*, and the potato crop which followed was lightly infested[8], even though the summer of 1940 was unusually hot and dry. But very cold winters are not characteristic of *maritime* seed areas. The contrary is demonstrably the case. To take as examples places in North Wales which have already been cited, minimum temperatures during January are higher at Holyhead than at Aber, and at Aber than at Sealand; while, to illustrate on a larger scale, the general run of winter minima is appreciably higher in the good seed areas of Ireland, North Wales and south-western England than in the English Midlands, and at least as high in the Scottish seed areas as in the Midlands[5].

Because they carry the taint of interference by irrelevant winter temperatures, aphid surveys in maritime climates must often be continued tediously for many years if they are to be sound. But speed is not the only advantage of the June temperature test. It is unaffected by the often remediable proximity of Brassicæ or other winter hosts. Further, being a test of the climatic conditions which govern the flight of *M. persicæ*, it measures the tendency towards migration; and the number of winged migrants to potato fields is, Whitehead[7] believes, a finer test of the aptness of an area for seed than the crude total of aphids, mostly wingless, which eventually multiply in the fields and are ordinarily the subject of a survey.

Wind has not been discussed, because its independence as a separate factor is questioned. It is true that Davies[2] showed in the laboratory that wind (above 3·75 m.p.h.) stopped the voluntary flight of aphids, but this does not imply that all wind is beneficial. In the maritime type of seed area a hot dry wind would be out of place and counter to the need for a cool temperature and a high relative humidity. All we can consider as unquestionably beneficial are cool, moist winds which, in the type of area under discussion, we can for all practical purposes take to be sea-winds. Their prevalence needs no elaborate system of wind roses for its measurement; it can be recognized simply by the intensity of the maritime influence on the climate, as determined, among other methods, by the June temperature test. In support of this view is the recognized fact that mere bleakness and high altitude are no adequate substitute for exposure to the sea.

The test applies only to a cool, maritime climate, and it would save confusion to point out that such a climate is only one of at least three in which infestation of potatoes by *M. persicæ* can be controlled naturally. The bulk of the world's seed potatoes is grown in areas with a cold, continental winter. These include most of the seed areas of continental Europe, of continental North America and (because the weather there moves from west to east) even most of the Atlantic seaboard of the United States and Canada. In these areas the requirements for good seed are very different. Finally, *M. persicæ* is scarce on potatoes in a very hot, dry climate, a fact systematically exploited in South Africa[11]. Here the desirable features are the opposite of those in a cool maritime climate: a mean maximum temperature during the summer months of about 90° F., a daily range of 28°–35° F. or more, and strong, hot, dry land-winds.

# ONTARIO RESEARCH FOUNDATION

ACCORDING to the report of the Ontario Research Foundation for the year 1943, that year saw a peak in the activities of the Foundation; for the first time since 1928 the problem of allotting laboratory space became acute. Some decision as to whether increased or permanent extensions are justified will be required in the near future. A second limiting factor has been the supply of trained research workers; until the demands from military departments and the war industries diminish, it will be impossible to devote adequate and sustained attention to post-war problems. The transition period might be shortened if research relating to post-war problems were given a higher rating in the system of controls and restrictions. It was not until shortly before the present War that any considerable use was made of the Foundation's facilities other than for routine services and short-term investigations, and at present the Foundation cannot establish enough fellowships to take care of the demand for research. This change is largely due to the gradual development and diffusion of a correct understanding of the relation between industrial scientific research and economic stability. It would add greatly to the stability and continuity of scientific research if the Governments concerned would encourage and not disallow the establishment of reserves for research.

The services of the Department of Engineering and Metallurgy have been almost wholly engaged on research or production associated with the War. The Gauge-Testing Laboratory has operated with approximately the same staff as in recent years. The gauges now being submitted by the inspection board of private manufacturers require steadily increasing skill and accuracy. The important contribution of the Physical Testing Laboratory is indicated by the increase in the number of test reports sent out from 350 in 1940 to 3,200 in 1943. The facilities have been improved by the addition of a 10,000-lb. tensile testing machine. The Heat-Treatment Laboratory handled 70 per cent more work than in the previous year. The general testing and short-term studies of the Textile Department slightly decreased. There exists in Canada a definite need for standards for moisture content of textiles, based on Canadian conditions of climate, and for an independent laboratory equipped to perform this service and issue certificates which will generally be accepted. A suggestion was made during the year that the Foundation should equip such a laboratory for testing wool

tops, but owing to the shortage of trained men response to the idea has not been possible. The process developed for setting the twist in rayon yarns has been in successful operation throughout the year, and a possible extension to the 'Nylon' field after the War is anticipated. Textile oils developed in the Department met all the requirements of the industry in plant trials. There is evidence that the consumer demand for quality-controlled goods is increasing.

The Department of Biochemistry has investigated on a pilot-plant scale some processes for producing glycerol from wheat, and the study of methods for hydrogenating linseed oil to plastic shortening has continued. The Vitamin Laboratory continues to study and evaluate the latest suggestions for determining quantitatively various vitamins in foods, and a study is in progress to determine the minimum amount of protein required to maintain rats in good health when the diet is adequate in all other respects. Research on synthetic rubber has been co-ordinated with that of the Canadian and American Rubber Committees. The possibilities of raising the quality of Buna *S* by addition of small amounts of chemicals to standard butadiene–styrene mixtures have been explored.

The Department of Agriculture has now collected all the material for a detailed map of the physiography of Southern Ontario, and has found that the photographs of the Royal Canadian Air Force offer a rapid method of obtaining accurate boundaries of physical land features. A thorough search has been made of geological literature relating to this and similar areas in preparation for writing a monograph of the physiography. A detailed study of regional agriculture in Old Ontario was continued; and in the Pathology Laboratory research was continued on problems associated with *Ascaris lumbricoides* infection of hogs, using guinea pigs in the experimental work, as well as on the blood parasites of ruffed grouse.

## SOUTH-EASTERN UNION OF SCIENTIFIC SOCIETIES

### ANNUAL CONGRESS

THE South-Eastern Union of Scientific Societies held its forty-ninth annual congress at High Wycombe on October 14—a single day of sessions and excursions attended by sixty representatives and members. It was organized by the Buckinghamshire Archæological and Architectural Society.

A representative assembly to transact the business of the seventy constituent societies was held in the Royal Grammar School, founded by the Knights of St. John and Jerusalem. For the ensuing year, Brigadier F. A. E. Crew was inducted as president of the Union. After many years as professor of animal genetics in the University of Edinburgh, he has recently been appointed to the Bruce and John Usher chair of public health at Edinburgh; and he is now serving at the War Office as director of biological research; his address was appropriately devoted to "The Biology of War". At the Guildford Congress in 1942, Dr. J. Ramsbottom in his address upon a similar theme (*Nature*, **150**, 241; 1942) came to the conclusion that "Competition in modern man is, for the most part, sociological and not biological". Brigadier Crew considers that "most of the causes of war have their origins, not in the biological constitution of man, but in the constitution of the social aggregates which man has formed and fashioned". Industrialized societies produce so full a routine of work which the ordinary man must carry out to earn a living that war may be welcomed for its stimulating excitement and loosening of conventional bonds. In brief, war is a great adventure because social conventions have not made an adventure out of peace. It is doubtful whether modern war is eugenically selective. "The lethality of a missile propelled from a gun or dropped from the skies has no relation whatsoever to the biological qualities of the man who releases it, and the winning of a combat or of a war is no proof of the biological superiority of the victor". There is a school of thought which teaches that war is definitely dysgenic. Possibly the flower of a generation is destroyed by war, but the flower is not so important as the seed and there is no proof that casualties in the War of 1914–18 seriously affected the physique of the present combatants. "Final victory in war rests with that contestant whose population is caused to increase more rapidly as the result of it." The present groups of mankind represent two widely different ideologies and cultures; it may matter very much indeed to humanity generally, for the next few generations at least, which of these shall prevail.

At the sectional sessions the following papers were read: "The Evolution of the Dwelling House", by E. Yates; "Archæological Work in Bucks", by Flight-Lieut. E. Clive Rouse; "Fungi as Food", by Dr. J. Ramsbottom; "Man and the Migration of Phosphorus", by Dr. K. P. Oakley; "A Plan for Local Social Science Workers", by A. Farquharson; and "The Fauna of New Guinea", by Miss L. Evelyn Cheesman.

In the afternoon, E. A. L. Martyn conducted a walk around Chipping Wycombe of interest to archæologists; naturalists visited Hughenden Valley, and others were shown the geological features of the district.

The annual congress is normally held in June, but this year it had to be postponed until the autumn as the original proposal to hold it in July at the Slough Social Centre proved impracticable. T. D.

## CURRENT MEASUREMENT AT VERY HIGH FREQUENCIES

A PAPER by G. F. Gainsborough entitled "Experiments with Thermocouple Milliammeters at Very High Radio Frequencies" (*J. Inst. Elect. Eng.*, **91**, Part III, No. 15; Sept. 1944) describes work conducted at the National Physical Laboratory under the auspices of the Radio Research Board. In order to assess the performance of commercial thermocouple milliammeters at frequencies up to 700 Mc./s., a reference standard air-milliammeter was first developed by the author, following principles first described by J. A. Fleming in 1910. Each of two similar air cells connected by a capillary tube with a liquid index contains a resistive wire which can be heated either by an alternating or direct current. With a capillary tube of 1 mm. bore, and using a low-power microscope to observe the index, the apparatus described in the above paper gave readings of current of the order of 10 mA., which could be reproduced with an accuracy of 1 part in 1,000. The sensitivity

could be altered by using capillaries of different bore, and filaments of different resistance.

With the aid of this instrument as a reference, an examination was made of some ordinary commercial vacuo-thermocouple milliammeters, in which the heaters are made of various well-known resistance alloys, and the thermocouple is separated electrically from its heater. One type of instrument tested contained a heater of one of the nickel-chromium-iron alloys; and a calibration of this instrument showed that its readings were subject to errors of more than 25 per cent for currents of less than half the maximum, this error falling relatively sharply to about 1 per cent over the top third of the current range. An investigation of this phenomenon showed that the material of which the heater wire was made was ferromagnetic at room temperature, but that the Curie point occurred at about 70° C., which was well within the working temperature range of the heater when supplied with its normal current. A simple method of examining the magnetic properties of the heater wire provided a confirmatory demonstration of this effect, and also enabled other samples of wire to be selected with the Curie point outside the working temperature range. When some new thermocouple milliammeters containing heaters of this alternative material were calibrated against the air milliammeter at a frequency of 100 Mc./s., the readings of the new instrument were indistinguishable from those of the standard.

With the aid of the experience gained in this work, various patterns of vacuo-thermocouple instruments were designed for higher frequencies. Considerable care was necessary in arranging the calibrating apparatus; but the results showed that for the new instruments, which were made on a commercial basis, the calibration at 700 Mc./s. agreed with the low-frequency calibration within the limits of experimental error, which was not more than 1 per cent of the maximum current.

In the concluding section of his paper, the author points out that when two such instruments are connected in series as closely together as possible, their readings usually differ widely when the circuit containing them is supplied with current at 700 Mc./s, unless some unusually great precautions are taken. It is suggested that, in practice, the opportunities of applying such devices usefully as milliammeters will be few at frequencies greater than 100–200 Mc./s. Nevertheless, instruments of the types described will have wide applications of relative signal magnitude at higher frequencies, and they may also have an important use as milliwattmeters.

## WEST CUMBERLAND AND ITS UTILIZATION

THE industrial region of West Cumberland coincides in the main with the coalfield and has its foci in the ports of Whitehaven, Workington and Maryport. With a total population of 150,000, there were 35,340 insured persons in 1932 and 36,870 in 1937. Out of the 1932 total, no less than 15,577, or nearly 45 per cent, were unemployed, and West Cumberland was scheduled as a depressed or 'special' area by the Special Areas Act of 1934. A careful and detailed study[1] by Prof. G. H. J. Daysh (at present directing the regional research work of the Ministry of Town and Country Planning) has surveyed the rise and fall of the chief industries and serves to emphasize the overwhelming dependence on coal-mining, iron and steel—industries which were especially affected by the depression of the 'thirties. The activities of the Special Areas Commissioner, Mr. E. G. Sarsfield-Hall, aided by the West Cumberland Development Council, were accordingly directed towards securing a diversification of industry and particularly to attracting light industries able to employ the available female labour.

The War has seen not only a return of prosperity to the old industrial centres but also has witnessed the building of vast works in hitherto untouched country, thus extending very considerably the former industrialized area. The problem for the future is thus of even wider import than it was in 1939. In the White Paper on Full Employment, the Government has accepted the recommendations of the Barlow Commission relating to dispersal of industry, and it is almost certain that West Cumberland will be constituted a 'Development Area' in which the Board of Trade, as the responsible Ministry, will encourage industrial development. The appearance of a cyclostyled report[2] by a business man and practical engineer whose companies have works in the area is thus opportune, and in his plan Mr. W. C. Devereux suggests industries which will provide employment for an additional 9,145 persons (compared with 18,615 estimated to be required by existing industries). The new industries proposed fall into three groups: (*a*) textiles, including wool and rayon; (*b*) engineering and skilled metal work; (*c*) canning and processing of agricultural produce.

It is, unfortunately, far from obvious that the basic causes of depression in West Cumberland have been realized. With the development of electric power, industry, even heavy industry, is no longer tied to the coalfields, with the result that transport facilities have become the dominant factor in industrial location. Broadly speaking, West Cumberland is at the end (apart from limited sea-traffic through the ports) of a branch line both of railway and road from Carlisle, and the obvious location for new industry is Carlisle rather than the coalfield, since Carlisle is on a main route with Scottish markets on one hand and English on the other. The advocates of a main through west coast road, crossing the head of Morecombe Bay by a viaduct, have recognized the importance of placing West Cumberland on a main through road route with direct access to Lancashire. Incidentally, such a road would open up to tourist traffic the delightful stretch of coast, with its magnificent views of the Lakeland mountains, from Millom to St. Bees Head.

Physical planning is essentially the right allocation of land for all the varied needs of the nation, and the advent of the much criticized Board of Trade into the field of post-war planning creates many problems. The West Cumberland development area overlaps the proposed national park, and there is no doubt that if encouragement is given to the continuance of industry in some of its war-time locations, then the enormously important influx of wealth from holiday visitors will cease. Seaside holiday homes are at present occupied by munition workers: only a central planning authority can decide their rightful future use in the national interest.

# FORTHCOMING EVENTS

### Saturday, November 18

QUEKETT MICROSCOPICAL SOCIETY (at the Royal Society, Burlington House, Piccadilly, London, W.1), at 2.30 p.m.—Papers.

SHEFFIELD METALLURGICAL ASSOCIATION (at 198 West Street, Sheffield, 1), at 2.30 p.m.—Mr. R. A. Hacking: "Technical and Economic Problems in the Heavy Iron and Steel Industry".

### Monday, November 20

ROYAL SOCIETY OF ARTS (at John Adam Street, Adelphi, London, W.C.2), at 1.45 p.m.—Prof. E. Capstick: "Milk", (1) "Dairy Education and Technological Training" (Cantor Lecture).

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Discussion on "The Effect of Welding on Electricity Supply" (to be opened by Dr. H. G. Taylor).

ROYAL GEOGRAPHICAL SOCIETY (at Kensington Gore, South Kensington, London, S.W.7), at 8 p.m.—Mr. S. H. Beaver: "Minerals and Planning".

### Tuesday, November 21

ROYAL SOCIETY OF ARTS (DOMINIONS AND COLONIES SECTION) (at John Adam Street, Adelphi, London, W.C.2), at 1.45 p.m.—Prof. Daryll Forde: "Social Development in Africa and the Work of the International African Institute".

ROYAL INSTITUTION (at 21 Albemarle Street, Piccadilly, London, W.1), at 5.15 p.m.—Mr. F. C. Bawden: "Plant Viruses and Virus Diseases", (i) "The Behaviour of Viruses in Infected Plants".

INSTITUTION OF CIVIL ENGINEERS (RAILWAY ENGINEERING DIVISION) (at Great George Street, Westminster, London, S.W.1), at 5.30 p.m.—Mr. Hugh O'Neill: "Metallurgical Studies of Rails".

INSTITUTION OF ELECTRICAL ENGINEERS (RADIO SECTION) (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Discussion on "New Aspects of Post-War Interference Suppression" (to be opened by Mr. P. R. Coursey).

### Wednesday, November 22

ROYAL SOCIETY OF ARTS (at John Adam Street, Adelphi, London, W.C.2), at 1.45 p.m.—Prof. I. M. Heilbron, F.R.S.: "The New Insecticidal Material D.D.T." (Aldred Lecture).

INSTITUTE OF FUEL (MIDLAND SECTION) (at the James Watt Memorial Institute, Birmingham), at 2.30 p.m.—Mr. A. Stirling: "The Practical Aspects of Reheating and Heat Treatment Furnace Insulation".

PHYSICAL SOCIETY (COLOUR GROUP) (in the Physics Department of the Imperial College, Imperial Institute Road, South Kensington, London, S.W.7), at 3.30 p.m.—Mr. E. N. Willmer: "Retinal Structure and Colour Vision".

INSTITUTE OF FUEL (NORTH-WESTERN SECTION) (joint meeting with the LIVERPOOL ENGINEERING SOCIETY) (at the Municipal Annexe, Dale Street, Liverpool).—Dr. A. C. Dunningham and Mr. B. M. Thornton: "Mechanical Stokers for Shell Type Boilers" (Précis and Discussion).

### Thursday, November 23

ROYAL INSTITUTION (at 21 Albemarle Street, Piccadilly, London, W.1), at 2.30 p.m.—Prof. James Gray, F.R.S.: "Locomotory Mechanisms in Vertebrate Animals", (i) "Aquatic Locomotion—Fins as Propellers, Brakes and Mechanisms of Directional Control".

LINNEAN SOCIETY OF LONDON (joint meeting with the ZOOLOGICAL SOCIETY OF LONDON) (at Burlington House, Piccadilly, London, W.1), at 3.15 p.m.—Dr. Maria Skalińska: "Polyploidy in *Valeriana officinalis* Linn. in relation to Ecology and Distribution"; Mr. R. Winckworth: "From Linnaeus to Lamarck": Prof. F. Wood-Jones, F.R.S.: "Time and Lamarck" (the Discussion on the Lamarck papers will be opened by Prof. J. B. S. Haldane, F.R.S.).

PHYSICAL SOCIETY (at the Royal Society, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Prof. M. N. Saha, F.R.S.: "A Physical Theory of the Solar Corona".

### Thursday, November 23—Friday, November 24

IRON AND STEEL INSTITUTE (at the Institution of Civil Engineers, Great George Street, Westminster, London, S.W.1).—Discussion on "Blast Furnace Operation and Problems".

**Thursday, November 23**

At 11.30 a.m.—Discussion on Fuel Consumption.

At 2.45 p.m.—Discussion on Furnace Operation and Problems.

**Friday, November 24**

At 10.30 a.m.—Discussion on the Preparation of the Burden (with special reference to Ore Beneficiation and Sinter).

At 11.45 a.m.—Discussion on Refractories.

### Friday, November 24

PHYSICAL SOCIETY (OPTICAL GROUP) (in the Physics Department of Imperial College, Imperial Institute Road, South Kensington, London, S.W.7), at 2.30 p.m.—Mr. E. Wilfred Taylor: "Notes on the Evolution of the Inverting Eyepiece"; Instructor-Captain T. Y. Baker: "Achromatism of two Thin Separated Lenses and of a Cemented Doublet"; Mr. B. K. Johnson: "A New Modification of a Ray Plotter" (demonstration).

ROYAL INSTITUTION (at 21 Albemarle Street, Piccadilly, London, W.1), at 5 p.m.—Dr. E. F. Armstrong, F.R.S.: "The Gas Industry—Yesterday and Tomorrow".

INSTITUTION OF MECHANICAL ENGINEERS (in conjunction with the MANUFACTURE GROUP) (at Storey's Gate, St. James's Park, London, S.W.1), at 5.30 p.m.—Mr. C. A. Gladman: "Drawing Office Practice in relation to Interchangeable Components".

INSTITUTE OF FUEL (SCOTTISH SECTION) (at the Royal Technical College, Glasgow), at 5.45 p.m.—Dr. W. Reid: "The Mining of Coal".

### Saturday, November 25

ASSOCIATION FOR SCIENTIFIC PHOTOGRAPHY (joint meeting with the SCIENTIFIC AND TECHNICAL GROUP OF THE ROYAL PHOTOGRAPHIC SOCIETY) (at 16 Princes Gate, South Kensington, London, S.W.7), at 3 p.m.—Mr. G. Parr: "The Electron Microscope"; Dr. E. M. Crook and Mr. L. V. Chilton: "Photographic Materials for use in the Electron Microscope"; Dr. D. G. Drummond: "Applications of Electron Micrography in Textile Research".

# APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

CHEMICAL ENGINEER by an important Engineering Company in the Midlands—The Ministry of Labour and National Service, Room 432, Alexandra House, Kingsway, London, W.C.2 (quoting Reference No. C.2195.XA) (November 28).

SCIENTIFIC OFFICER (temporary) to take charge of the MATHEMATICAL and COMPUTATIONAL WORK of the Admiralty Computing Service—The Ministry of Labour and National Service, Room 432, Alexandra House, Kingsway, London, W.C.2 (quoting Reference No. A.702.A) (November 28).

WATER ENGINEER—The Clerk to the Trowbridge, Melksham and District Water Board, 22 Silver Street, Trowbridge (endorsed 'Water Engineer') (November 30).

SPEECH THERAPIST—The Director of Education, Education Office, 8 City Square, Dundee (December 1).

DEMONSTRATOR IN HUMAN PHYSIOLOGY, and an ASSISTANT KEEPER to be responsible for the Zoological Collections in the Manchester Museum—The Registrar, The University, Manchester 13 (December 1).

ENGINEER (Water Supplies) by the Gold Coast Government Public Works Department—The Ministry of Labour and National Service, Room 432, Alexandra House, Kingsway, London, W.C.2 (quoting Reference No. E.1094.A) (December 11).

AGRICULTURAL SCIENTIFIC OFFICERS (temporary) on the staff of the National Institute of Agricultural Engineering, Yorks.—The Ministry of Labour and National Service, Room 432, Alexandra House, Kingsway, London, W.C.2 (quoting Reference No. F.3066.A) (December 11).

GEOPHYSICIST (temporary), a GEOLOGIST (established), and a GEOLOGIST (temporary), on the staff of the Geological Survey, Department of Industry and Commerce—The Secretary, Civil Service Commission, 45 Upper O'Connell Street, Dublin (December 20).

TECHNICAL ASSISTANT IN THE ELECTRICITY DEPARTMENT—The General Manager, Electricity Offices, Ferensway, Hull (January 1).

LIBRARIAN—The Secretary, Society of Antiquaries of London, Burlington House, Piccadilly, London, W.1 (January 31).

CHAIR OF ENGINEERING—The Secretary, The University, Aberdeen (March 31).

SENIOR LABORATORY ASSISTANT IN THE DEPARTMENT OF ZOOLOGY—The Secretary, Bedford College for Women, Regent's Park, London N.W.1.

PRINCIPAL OF THE MERRIST WOOD FARM INSTITUTE, Guildford—The Chief Education Officer, County Hall, Kingston-upon-Thames, Surrey.

RESEARCH WORKER on the nature and composition of the anti-anæmic principle in liver, and a RESEARCH WORKER to prepare and employ purified or crystalline digestive ferments—The Courtauld Institute of Biochemistry, Middlesex Hospital, London, W.1.

HYDROGRAPHICAL SURVEYOR for the Basrah Port Directorate, Iraq—The Ministry of Labour and National Service, Appointments Department, Sardinia Street, Kingsway, London, W.C.2 (quoting Reference No. A.4962.S).

TEACHER FOR PHYSICS AND CHEMISTRY—The Acting Principal, Technical Institute, Sheerness, Kent.

HORTICULTURAL ADVISER (man) and an ASSISTANT HORTICULTURAL ADVISER (man or woman)—The Chief Education Officer, County Hall, Kingston-upon-Thames, Surrey.

# DISSEMINATION OF SCIENTIFIC INFORMATION

THE well-deserved tributes which have been paid to the achievements of British and other men of science in war-time almost inevitably tend to encourage in the public mind the belief that war stimulates scientific advance. That notion was exposed in "The Frustration of Science" (published by Allen and Unwin, 1935); but it is well to be reminded that, despite certain gains, on balance war tends to retard rather than to promote general advance. The advances occur in limited fields where the prosecution of the war effort is directly served, and although such advances may be turned to account in peace-time, the scientific effort expended is sometimes out of proportion to that which might have achieved the same result in peace-time. Moreover, fundamental research tends to be suspended entirely, or at best is pursued with inadequate means.

The positive achievements of scientific effort in war-time should not, therefore, be allowed to obscure the fact that a heavy price has been paid, that important fields have been neglected, and that development at best has been lopsided. It might be exaggeration to speak in the present war of the frustration of science; but there can be no denial that advance generally has been impeded, and a main cause of this has been the interruption of communications between scientific workers, both within and across national boundaries. The interruption of internal communications has already been the subject of some discussion in regard to the organization and development of scientific and industrial research in Great Britain. The international aspect is discussed by Dr. Joseph Needham in an article appearing on p. 657 of this issue.

It is, of course, to remedy the position which arises from the interruption of free scientific intercourse across national frontiers, with all that such intercourse means in the exchange of knowledge and ideas and the stimulation of creative thought, that there have been established in war-time such organizations as the British Central Scientific Office in Washington, the American Scientific Office in London, the scientific liaison officers of the various Dominions with the United Kingdom, the Anglo-Soviet Science Collaboration Committee and the Scientific Co-operation Office of the British Council in China, the organization and work of which Dr. Needham describes in some detail. It is no disparagement of the services of such liaison organizations to point out that some at least of their work in war-time is due to the interruption of normal channels of communication and the operation of the censorship. No such organizations, however efficient, can entirely compensate for the effects of withholding a scientific or technical paper either from publication entirely or from communication abroad.

In considering any new proposals for the organization of co-operation or the exchange of information in science, it is well to recall that the progress of science depends first and foremost upon full freedom of investigation and expression, and the first step

must be the removal of the constraints of war-time at the earliest possible moment consistent with world order and security. Organization, in fact, should be not a substitute for such intercourse, as in war-time it tends to be, but a supplement and a stimulant.

As to the need for such supplementing, there is little room for doubt. The report issued last year by the British Commonwealth Science Committee (see *Nature*, 152, 29; 1943) showed how much remains to be done to improve the collection and dissemination of information and collaboration in research within the Empire, while the necessity for extending such collaboration to the United States, the U.S.S.R., China and other countries or regions was clearly indicated by the Committee. The report recommended specifically the maintenance in London by the Governments of the English-speaking countries of permanent scientific and technical representation, and that such representatives of the Dominions and India and of the United Kingdom and the Colonies should constitute a British Commonwealth Scientific Collaboration Committee, to act with the Royal Society in the discussion of topics of common interest, to keep in touch with all agencies and organizations for the collection and dissemination of scientific information, to further schemes for co-operation in research, and to make recommendations and proposals for common action. Arrangements to secure the co-operation of similar representatives in London of the United States and of other countries outside the British Commonwealth were also recommended.

Already the Council for Scientific and Industrial Research in New Zealand, the National Research Council of Canada and the National Research Board of South Africa are prepared to support such collaboration, and Prof. A. V. Hill has expressed the hope that such co-operation will lead in due course to more general collaboration. There is thus in being a movement which promises to retain the science co-operation offices already established for war purposes, and to use for post-war purposes at least their 'post-office' functions. Much more than this is clearly contemplated by the British Commonwealth Science Committee, which in its report has boldly indicated some of the possible developments in the collection and dissemination of scientific information, such as collaboration in the production of scientific abstracts for the common use of the English-speaking world.

These tendencies, to which Dr. Needham directs attention in outlining his proposals, are reinforced by others, the importance of which has been enhanced since the appearance of the British Commonwealth Science Committee's report. If the value of the various agencies for co-operation in science set up under the stress of war in the capitals of the United Nations is becoming more generally appreciated, the importance of utilizing such machinery for peace purposes has also been generally emphasized. There is now general agreement as to the mistake which was made in 1918–19 in scrapping too easily and without examination the similar organizations established then for our war purposes. Furthermore, as Dr. Needham notes, the whole trend towards the establishment of functional bodies such as the United Nations Relief and Rehabilitation Administration and the Food and Agricultural Organization enforces the need for more effective co-operation in science across national boundaries. Unless that is established, the functional bodies can scarcely achieve full success.

Whether the structure of the new world order is essentially functional or regional, such scientific collaboration will be essential, and its value has been proved by the work of such bodies as the Middle East Supply Centre and the Anglo-American Caribbean Commission. It is also in line with the school of thought which, inspired by the achievements of the Tennessee Valley Authority, looks to the development of Europe's public utilities or such regional projects as a Danube Valley Authority. There is, moreover, all the experience of the League of Nations' technical committees to testify to the feasibility of such co-operation in matters like health, the opium traffic, communications and transit.

But there is a further reason why the organization of such co-operation is important, which is well brought out in a recent article on "Intellectual Co-operation" by Dr. Gilbert Murray in *Agenda*. Whatever form the world organization for peace tentatively outlined in the Dumbarton Oaks proposals may ultimately take, whether its basis is regional, functional or whether ultimately it develops into a federal system, there must be some community of thought, some general understanding of the unexpressed assumptions, attitudes of mind, characteristic of each national tradition and taken for granted by those who share that tradition. To discover and interpret such assumptions is the primary task and function in international intellectual co-operation, which in this way by encouraging the artistic, scientific and imaginative links between the nations, promotes continuous co-operation and has a powerful, though unseen, influence for good.

By and large, much of this intellectual co-operation must be by personal intercourse and conversation between the people concerned. On that fact rests part of the case for an international university, put forward, for example, by Prof. G. W. Keeton in "The Case for an International University" (Watts, 1941), with its twin functions of the organization of research into all those problems which arise in the achievement of a world-order and publication of the results of such investigations, and the teaching of the adult communities and of youth so as to develop an ordered nationalism, seeking to establish the place of individual national cultures within the general pattern. But such co-operation must not be limited to the university level; it should permeate all aspects of national culture if it is to provide the broad basis of goodwill for world order.

When all allowance is made for the limitations of space, the most striking impression which Gilbert Murray's survey makes is the comparative neglect of the scientific field. This statement that the agreement made in 1937 between the Committee of Intellectual Co-operation and the Council of Scientific Unions bore particularly good fruit might be disputed. In the scientific field, intellectual co-operation appears to have been largely sterile, and this conclusion is

supported by the paper which Dr. Arnold Raestad contributed to the British Association Conference on Science and the Citizen last year (see *Advancement of Science*, 2, No. 8, 289 ; 1943). At the session on the exposition of science, Dr. Raestad, to whose paper Dr. Needham refers, reviewed generally the work of the Institute of Intellectual Co-operation leading to the appointment in 1938 of a committee to consider the means of improving the organization for presenting the results and methods of science to the general public ; and then described the main objectives of an international centre for scientific information, the creation of which was recommended by that committee.

These objectives were, first, the continuous recording of the progress of science, and, secondly, the mobilization, as need and demand arose, of information on any scientific point of current interest. With a modest central secretariat and regional representatives, it was proposed to work through the appropriate academy of science or other scientific body in each country that respected freedom of scientific thought and expression. Nations which subordinated scientific research to racial or other prejudices were to be excluded. The functioning of one such national centre of information, started in Paris in 1939 by the French Government's National Centre for Scientific Research, was described by Mr. J. G. Crowther at the annual conference last year of the Association of Special Libraries and Information Bureaux, based on information supplied by M. Louis Rapkine. This centre, directed by Prof. Pierre Auger, was essentially concerned with the provision of information by the expert, while the proposed international centre for scientific information was intended, at least in part, though not exclusively as Dr. Needham seems to think, with the education of the general public. The latter is, of course, the prime purpose of the institute of scientific information suggested by Mr. Ritchie Calder at the same British Association Conference. The very successful work of the British Council in this field is apparent from its latest annual report, and such work is of vital importance to the stability of a new world order or organization for peace. Such an order must rest on a greater readiness, and even habit, to submit one's own judgment to the control of facts, and to respect in others the supreme freedom to ascertain and assess facts, as Dr. Raestad emphasized.

That is a prime reason why implementation of international co-operation in the exposition and interpretation of science is of such importance to the establishment of world peace. The experience of the International Unions and of the Committee on Intellectual Co-operation suggests that the more effective organization of scientific co-operation may have equally important results in scientific circles themselves. It at least offers the prospect of breaking down some of the insularity and rigidity to which national professional organizations are inevitably prone, of stimulating that fundamental and creative thinking about their functions for which Prof. A. M. Carr-Saunders and Mr. P. A. Wilson pleaded in their study of the professions. Scientific workers, at least collectively in their professional associations, have been singularly blind to the possibilities which technical developments such as the microfilm or air transport hold for the improvement of their own ancillary services such as abstracting and publication, and the picture Mr. Crowther gave at the Conference of the Association of Special Libraries and Information Bureaux of the work of the French National Centre was most suggestive.

This, then, is the broad background against which Dr. Needham's proposals for the establishment by the United Nations of an international science co-operation service, as a functional body parallel with the International Labour Office and the Food and Agricultural Office, have to be considered. This would presumably fit in under the Economic and Social Council of the Dumbarton Oaks proposals, and could possibly be financed on similar lines. The permanent headquarters of the service would probably be determined by the centre selected as the headquarters of the general international organization, though, apart from the central and peripheral permanent secretariat, a considerable proportion of the officials of the service should, in Dr. Needham's scheme, be working men of science, selected to ensure that the organization always preserves the true atmosphere and understanding of research.

The functions of this international science co-operation service are to be the promotion of all aspects of scientific co-operation, the collection and dissemination of scientific information, the furtherance of schemes of research collaboration, facilitation of the movement of scientific workers across national boundaries, provision of advice on scientific matters to government and diplomatic personnel of individual States when desired and the provision of scientific assistance to all international organizations. Dr. Needham gives no clear idea as to how the new organization is to be developed from existing organizations, although he indicates some which might be linked up with it at a later date. His suggestion that the service should have permanent representatives in all countries or regions might be taken to indicate that he visualizes it as developing out of the scientific offices at present maintained in London, Washington and Chungking. This further proposal that such representatives should have diplomatic or 'League official' status and guaranteed government facilities for communication and transport reflects the suggestion made by Lord Samuel in the House of Lords last year regarding the appointment of scientific attachés to the principal British embassies abroad, or that Great Britain may have liaison officers who can bring to the notice of those interested at home the progress and methods which have been achieved or established in other countries.

The question of diplomatic status is a detail that requires somewhat fuller consideration when the proposals have reached the stage of a definite scheme. It is true that, as current criticism of the Foreign Service has emphasized, the basis of recruitment of that service requires widening, that it is important it should include those qualified to recognize important scientific and technical developments abroad and

to advise authoritatively on problems of science and technology. There is, however, also the question of loyalties, and in conveying science and technology from the industrially advanced Western countries to the less advanced Eastern ones, confidence in such advisers as genuinely unbiased and disinterested may best be fostered if their first loyalty is seen to be unmistakably to science. Diplomatic facilities might be too dearly bought if they involved any compromise in that fundamental loyalty to the pursuit of science.

The proposals that Dr. Needham has advanced merit the serious attention of scientific workers. The case for some substantial improvement in what may be termed the 'communications of science', both inside its own special field and in its exposition to the public generally, is unchallengeable. That development must be a vital part in the new world organization to be established and for the success of new functional or regional institutions. Moreover, the proposals represent a challenge to existing professional associations, which, if accepted, may have invaluable consequences for the advance of science itself by the improvement of contacts, the stimulation of creative thought, the adoption of new techniques of communication and the facilitation of co-operation across and within national frontiers in the attack on the many problems the solution of which is imperative if mankind is to enjoy the bounty which science has put within our power to command. How great are those possibilities can be glimpsed from the stimulating survey of the study of land settlement to which Dr. Isaiah Bowman devoted the greater part of his presidential address, "Commanding our Wealth", to the American Association for the Advancement of Science last September (*Science*, **100**, 229; 1944). One of the roots of the tree of peace, he urged, is science; but if a true science of land settlement is to emerge, if we are to harness to the affairs of peace, as the Prime Minister said in his broadcast from Quebec last year, science, good sense and experience as well as hope, there must come first the removal of barriers of regulation or misunderstanding, tradition or prejudices hindering the free communication of information and interchange of men of science or of ideas throughout national and international life. After that will come new organizations, on the evolution of which in appropriate forms fresh, critical and unprejudiced thought and sound judgment must be brought to bear.

## A SURGEON LOOKS AT MEDICAL EDUCATION

### Rational Medicine

Comments on Social Medicine, Surgery and Education. By Basil Graves. Pp. xi+292. (London: Nicholson and Watson, Ltd., 1944.) 12*s*. 6*d*. net.

THE author of this book is an ophthalmic surgeon. His original purpose, he states, "was to describe and suggest the reform of certain anomalies that exist in present-day educational and surgical practice". As he proceeded in this enterprise, he encountered other lions in the way, in pursuit of which he has wandered down side-paths far removed from the beaten track. These digressions, in spite of a fluent style and much erudition, make the book difficult reading and involve much repetition.

In discussing the question of specialism, Mr. Graves draws chiefly on his own experience. He cites several unhappy examples of men who, despite high professional qualifications, have bungled operations on the eye. He avers, and no doubt with truth, that some surgeons are unfitted by training or experience for the specialty they profess. He rightly castigates the pseudo-specialist and the fetish of a brass plate in some particular street; and barbs the arrows of his attack with anecdotes and quotations. This criticism of his professional brethren is not vindictive. He remembers that most of them do excellent work, have a high sense of their calling and endeavour to mitigate the lot of human suffering. He holds that often incompetency results from unsuitable training, which has comprised general surgery and memory tests bearing little relation to future specialized work.

The truth of the matter is that medical examinations, qualifications and postgraduate diplomas testify to a man's reading and intellectual capacities, but to a considerable extent they also assess a candidate's clinical competence in diagnosis and treatment. The wealth of new knowledge that has enriched medicine during the past fifty years has greatly over-burdened the student of medicine with theoretical data; but all experienced examiners will agree that final and postgraduate students who fail do so chiefly in the clinical part of their examinations.

No man should presume to engage in specialism on academic qualifications alone and without a prolonged period of practical experience in hospital under the direction of recognized authorities. Only a minority have departed from this usual procedure, and those who have done so have usually regretted it. The incompetent surgeon, even if he buries his failures, gets weeded out and betakes himself to some other branch of the profession.

Mr. Graves considers that few important individual contributions to general knowledge have come from famous surgeons, though he admits Wilfred Trotter was an exception. But one could compile a long list of surgeons who have made such contributions. Sir James Paget and his son, Stephen Paget, Sir Frederick Treves, Sir D'Arcy Power, Sir Rickman Godlee, Prof. Grey Turner and many others. Sir Victor Horsley was not only a great cerebral surgeon and physiologist, but he was also a social reformer. The examinations for the fellowship of the Royal College of Surgeons of England cannot always cripple reflective thought as Prof. Tonks supposed (p. 23). Indeed, being himself a holder of that diploma, his own career as an artist refuted the statement.

The author rightly considers that there should be no social distinction between intellectual and manual work, and he extols the beauty of craftsmanship. The pity of it is that mass production and modern industrial processes are gradually eliminating the craftsman, with his appreciation of beauty and love for the work which grew under his hands. The medical profession itself is a blend of intellectual and manual labour, for the medical student from his pre-clinical days is trained how to use his hands, as is the student of science in physical, chemical and biological studies. He or she must be both thinker and craftsman.

Mr. Graves's views on the defects in the system of general education are specially endorsed by Sir John Graham Kerr in an appreciative foreword to the book. There is the waste of time devoted to rote-memorizing "with its disastrous interference with the development of originality and character, and with other things that really matter: as in the case of hospital nurses whose training in the very human and womanly art of nursing suffers from the amount of time demanded for the memorizing of masses of detail relating to anatomy and physiology; and the greatly exaggerated importance attached to written examinations as a means of testing ability". The main aim of education should be to develop the biological worth of the individual. With these arguments, which are reinforced by quotations from the educational experiences of Winston Churchill, H. E. Gorst, William James, Herbert Spencer, A. J. Balfour, Bernard Shaw and Thomas Huxley, most readers will be in agreement.

Mr. Graves also deals with a most important point. Boys and girls have to prepare for examinations at a time when they are already exposed to the strain of adolescence. This combination of physical and mental strain is most unfortunate, and occasionally leads to disastrous results. Examinations are possibly necessary evils, but because some children develop intellectually early, others late, they are imperfect tests of future mental ability. We must resist the educational 'gradgrinds' who, on the result of examination tests, would put every child into permanent intellectual pigeon-holes at the age of fourteen or sixteen years.

Mr. Graves admits he is on less firm ground when he comes to remedies for his present discontents. His suggestion, for example, for evaluation of a surgeon's operative skill—even by slit-lamp examination in ophthalmology—will scarcely prove acceptable in practice. As the author himself points out (on p. 50), the surgeon deals with living tissues the reactions of which cannot by any means always be determined or controlled, so that a case may prove disappointing even though the patient has received most competent specialized attention and the most skilful operating procurable.

Reform is, however, on the way, and in many directions. The Royal College of Surgeons is considering the practicability of instituting a special F.R.C.S. diploma in ophthalmology, which should go a long way to meeting the author's criticisms of the present examination. Furthermore, since this book was written, Sir William Goodenough's Inter-departmental Committee has reported on medical education: in its recommendations more attention is to be paid to clinical experience, less to rote-memorizing, while every candidate, it is proposed, should have a compulsory period of hospital appointments after passing the final medical examination before being admitted to the medical register.

Concerning a State medical service, Mr. Graves advocates an intermediate attitude, and his views seem likely to receive much general support from the profession.

This is a controversial treatise, and not all the writer's contentions will be acceptable. Enough has been said to indicate the book's earnest purpose and its provocative and challenging character. Its appearance is timely, for many of the questions it propounds are now being discussed by the medical profession and by all those who are interested in health and social reform.

ARTHUR S. MACNALTY.

## SCIENTIFIC METHOD IN ECONOMIC PROBLEMS

### The Future of Economic Society

A Study in Group Organisation. By Roy Glenday. Pp. viii+320. (London: Macmillan and Co., Ltd., 1944.) 16*s*. net.

THIS book claims in its first sentence to be an "attempt to apply the scientific method to the study of economic problems", and to readers of *Nature* the question of prime importance must be how far Mr. Glenday has succeeded in this difficult task.

The early biological chapters, the constant reference to statistical data, the obvious wide reading of the author create a favourable impression. Here obviously is a scientific work, in so far as 'scientific' means both taking account of the conclusions of other sciences such as the natural sciences, and beginning with the observed and measured facts of your own science, in this case the facts of human society.

It is true that the author has the habit of attacking economists somewhat indiscriminately, even those like Colin Clark who have tried to pursue the same scientific method. It is true, too, that the author arrives at conclusions even more gloomy than those of the 'dismal science' itself. He finds that the high unemployment suffered in the inter-war years is not just a passing phase, but (p. 176–7) "the accepted index that a given organization is in process of breakdown", and that "superficiality of diagnosis seems to underlie the popular theory that the problem of persisting unemployment could have been solved either by the institution of public works, the equating of savings to investment—or, if all else failed, by setting those out of work to provide for their own needs". To quote Mr. Glenday's own summary, he foretells (p. 19) that "the days of the present economic society are numbered", meaning by this a society based (p. 20) on the ideal of the intrinsic uniqueness of individual man as against that of the subordination of the individual to the community. But however disputatious the attitude or gloomy the prophecies, a scientific critic must be put off neither by the incidental fireworks of controversy nor by the unpleasantness of the findings. He must inquire into the validity or otherwise of the *basic* conceptions and methods underlying the results.

At least two serious flaws appear to me in the structure of the argument. The first is the assumption that continuous geometrical progression must be expected; and if it is not attained, but merely arithmetic additions, that there is cause for despondency. Yet, as the series 1, 3, 6, 10, 15 exemplifies, it is quite possible for a continuous fall in growth-rates also to show a continuous rise in additional increments. Occasionally, indeed, Mr. Glenday must be accused of dressing up his graphs for the funeral pyre. There is a depressing diagram (Fig. 5, p. 78) showing the decline in growth-rate of five important items in American economic life between 1840 and 1930. In four of these—railroad mileage, steel tonnage, automobile registrations and electric power—the curves plunge downward catastrophically. But what are the facts of America? A continuous addition in all these items per head of population, compared to which the falling geometrical rate of growth is frankly just an academic abstraction.

The second flaw in Mr. Glenday's argument is his piecemeal approach. He takes a number of separate industries and shows statistically that their rate of

growth is falling, and in some cases that they are arithmetically declining. But this does not allow for the fact that some industries are failing because more efficient methods of doing the same thing, or of doing better things, are taking their place. Railroad track mileage, for example, might well be declining absolutely because motor roads were substituted for purposes of transport. But there is no reason to be gloomy about it. On the whole, social progress has involved changes in consumption in the shape of substituting more intangible and variegated goods and services for easily measured staples, so that there is here a special risk that statistics, more easily obtained for the tangible output, may often be misleading for standards of consumption as a whole. In fact, attempts by economists such as Prof. A. L. Bowley, Mr. Seebohm Rowntree and Mr. Colin Clark to assess the total national real income by scientific methods of statistical computation show for Great Britain a continuous increase in goods and services per head of population during the twentieth century, with no sign of fading out.

The parts of the world where gloom may be scientifically justified are the 'have not' countries, where increasing production is simply allowing more and more population to stay alive and to keep down the *average* standard of living per head. These Malthusian conditions to-day affect countries containing at least four-fifths of the human race; but Mr. Glenday (p. 253) purposely omits them from his thesis.

Ancillary to Mr. Glenday's main thesis, many problems are discussed that arouse great interest. Notable among these are the satiation of wants (p. 204), where the author seems to under-estimate the possibilities of raising the consumption of the poor by those very social charges he deplores; and the problem of co-ordination (p. 186) arising from the distance separating the main food-producing areas from the industrial areas of the world.

Mr. Glenday writes clearly and without circumlocution. Though he does not prove his main thesis, and is handicapped in interpreting the facts by neglect of the useful apparatus of thought provided by economics, yet his book does at least tackle the essential dynamic problem of the trend of events, does start with the facts, and does present them forcibly.

P. Sargant Florence.

## SOCIAL HUMANISM

### The Humanities Look Ahead

Report of the First Annual Conference held by the Stanford School of Humanities, 'The Humanities in the War and Postwar World', May 7 and 8, 1943. Pp. ix+149. (Stanford University, Calif.: Stanford University Press; London: Oxford University Press, 1943.) 10*s*. 6*d*. net.

In many ways the conference at Leland Stanford University, at which the seventeen papers collected in this volume were read, was characteristically American. It was as ready with self-criticism as with plans for action. Now that the arts, true science and philosophy are all "dislodged and beaten almost beyond surviving there in Europe and Asia", for the first time the United States of America, in the words of Prof. Paul Green, had leadership in this field thrust upon her. They met, however, "not to save the humanities" but to find the conditions "under which they would be worth saving". It was natural to begin the quest with an attempt to find out what was wrong with them now, and the speakers agreed on two main points. The humanistic field itself had become divided between, on one side, a few small groups living complacently a life of intellectual preciosity, who had forgotten that humanism had to serve humanity, and on the other side, a frightening array of people engaged on 'exact' research who had little sense for what Croce has called 'the feeling of the living soul'.

The second general cause of that decline was the growing gap between humanism and science. Prof. Frederick Koenig attributed that to the enormous growth and specialization of science, which had left the several disciplines high and dry as isolated islands, no longer fertilized by a common stream of philosophy; a separation accentuated by difference in temperament between the practitioners. The "scientists are unable to see that artists have brains, and artists are unable to see that scientists have souls". In such conditions humanism could not inspire the individual, in Symond's definition, with a "vital perception of the dignity of man as a rational being", or achieve its wider academic function, as defined by Dr. Leland, of "bringing understanding out of knowledge". The role of the humanities in their academic precincts and functions was indeed the central theme of the discussion; and while "Social Humanism" was the title of Prof. Borgese's paper, with its passionate generalities and its call for a 'Republic of the World', the British reader will find its substance rather in the papers which described American experience and experiments. Dr. Waldo Leland, the distinguished director of the American Council of Learned Societies, put the problem acutely when he said that it was "how to make human energy intelligible to itself". (Dr. Leland incidentally announced that his Council was about to publish a report on the part of the humanities in a liberal education.)

To the general causes for their decline, Dr. Leland added a more practical one, namely, the excess of students, with the resulting dilution in the qualifications of both students and teachers. Closely allied with over-specialization was the failure to keep up an active inter-relation with the sciences and, especially, with the social sciences; and last, but perhaps most serious, the failure of many scholars to "concern themselves actively with education". That was perhaps as true of men in the sciences, but for the humanist education was the very soil he had to till. The function of the humanist was so to inspire the learner that he may "develop for himself not a career but a character", said Mr. David Stevens, of the Rockefeller Foundation, who gave a survey of the Foundation's practical work in this field during the past ten years. Prof. Waldo Dunn described an experiment in humanistic education at Scripps College; and Prof. Linden Mander that of Washington University, where by various means the University is trying in characteristically practical ways to widen the range permeated by its educational work. All that corresponded to the two conditions which the conference seemed to think necessary for reclaiming the humanities: first, some unity of philosophical outlook in the world of thought and, secondly, the permeation with it of man's world of action. Two quotations from Mr. Lewis Mumford's final paper on "The Making of Men" may serve to round off an inevitably inadequate summary of this lively conference: "Our mistake consists in thinking that there

is anything final or absolute in the present form and traditional methods of the university, and in not seeing that if only a profound change in all our cultural habits will save our civilization, we must plan and effect that change". "But here we must transcend the limitations of our own humanist tradition : for the first step toward world co-operation must rest on our realization that the humanities are not a special creation of Western civilization. . . . Unless we are humble enough to learn from all these sources", humanists will miss the opportunity of "carving out a much larger and much more significant place for themselves than they have ever occupied before". DAVID MITRANY.

## THE EXPANDING LIBRARY

**The Scholar and the Future of the Research Library**
A Problem and its Solution. By Fremont Rider. Pp. xv+236. (New York: Hadham Press, 1944.) 4 dollars.

THE growth of American research libraries, averaged together, according to figures quoted by Mr. Fremont Rider, shows a doubling at almost exactly sixteen-year intervals, and there seems no good reason for believing that the rate of growth will be seriously checked for many years to come. If unchecked, the figures for some of America's largest libraries will become astronomical. Though, for a variety of reasons, the rate of growth of British libraries is not equally rapid, there is much of value and interest to be found in Mr. Rider's examination of the problems involved and in the suggested solution.

In the first part of the book, Mr. Rider recapitulates various current methods of reducing the growth of research libraries, and shows why they cannot be wholly satisfactory. He is entirely concerned with the problem of the research library serving the more advanced type of reader; comparable, in fact, to British national libraries such as the British Museum or the Bodleian. In such libraries it is an axiom that no class of material can be discarded with impunity. Even the trivia of to-day may prove valuable in relation to sociological or biographical research a century later. The scholar's needs are casual, but they are also urgent and unpredictable. In a satisfactory service he expects, within reason, to have his material available for quick consultation.

Mr. Fremont Rider's solution lies in 'micro-cards'. By this term he means the reproduction, in micro-print, of the text of the book or paper itself, on the back of a catalogue card. The face of the card would show the catalogue entry and an abstract of the work, in print of ordinary size. A careful choice of the form of the catalogue entry would enable the same cards to be used for author, title or subject catalogues, thus doing away with the need for further copying or additions by the subscribing libraries. Mr. Rider specifically suggests the use of the 'Readex' process, by which it is possible to print 100–250 pages of a book on a standard library card, but other adaptations of micro-photography are also possible. The resulting economy in space and cost is obvious.

The second half of the book deals with the micro-cards, their format, publication and uses, and with the problems of copyright. Mr. Rider stresses the fact that success in the use of micro-cards will depend largely upon an agreed format for the catalogue entry and subject headings, since interchangeability of cards among the subscribing libraries is an absolute necessity. It is therefore of great importance that the cards should be made, in the first place, by bibliographical experts. Mr. Rider recommends an extension of the division-of-fields suggestions already put forward by the Metcalf Committee. According to these proposals, each of the co-operating libraries would select its own particular sphere of interest and would endeavour to collect all research material pertaining to this field. Mr. Rider suggests that each of the co-operating libraries, thus having at hand all data relevant to its own field, would be in the best position to draw up the most accurate catalogue entry and subject classification for such material. Each library should therefore issue the micro-cards for works within its own field, receiving in turn micro-cards from other libraries specializing in other fields.

Objections to the schemes proposed by Mr. Rider could be immediately suggested, but much remains that is worthy of close attention. Micro-print, as distinct from micro-film, is still in the early stages of evolution, and reader-machines are in short supply. It may, however, reasonably be anticipated that supply will follow demand and that improved technique and equipment will rapidly be developed.

The method of combining the legible catalogue entry with the actual text of the original eliminates many of the disadvantages of micro-film and has much to recommend it as a self-contained and rapid means of access to reference works. Those who have felt that the potential value of micro-photography as an aid to the solution of library problems has not yet been fully utilized should draw inspiration from this book. E. M. R. DITMAS.

## BRITISH PLANT DISEASES

**List of Common British Plant Diseases**
Compiled by the Plant Pathology Committee of the British Mycological Society. Pp. 61. (Cambridge: At the University Press, 1944.) 5s. net.

SO far back as 1928 the British Mycological Society decided to appoint a committee of men of science interested in plant diseases, their object being to compile a list of the more important diseases of British crop and ornamental plants and to suggest for each disease a single selected common name. It was hoped to encourage the use of these selected names so that uniformity in the naming of plant diseases could be achieved at least in the British Isles. Many people dealing with plants must be aware that the same disease of a particular plant may be known by several common names according to the locality, and furthermore that a name is often quite unsuitable for describing the disease to which it refers.

The Committee produced its first list in 1929 in the *Transactions of the British Mycological Society*, **14**, and further improved on this by publishing a second edition of the list in book form in 1935.

It has now produced in book form a third edition, with various emendations and additions, printed as before in two parallel columns, on the left the name of the host plant with, under it, the recommended common names of its diseases, and on the right the scientific name of the parasite causing the disease. In the case of diseases not caused by

fungus or bacterial parasites the right-hand column gives the name of the causative agent, for example, mosaic virus, manganese deficiency, irregular water supply, etc. There is one important change in lay-out as compared with previous lists, this being the fact that the host plants instead of being arranged in groups, such as fruits, vegetables, etc., are now all placed in alphabetical order according to their names as ordinarily used. The result is that there is no need for a host-plant index.

In the case of the more important diseases which are also prevalent abroad, foreign common names from several countries are given in slightly smaller type under the selected British common names. There are an index of authors' names and abbreviations, one of the accepted scientific names of both host plants and parasites, and one of foreign common names of various diseases. Many readers will note and approve the separate index providing common names of diseases in Russian.

This attempt at uniformity in nomenclature of diseases is to be commended in a field where confusion is still too often met with. The fact that changes repeatedly occur in the scientific names of plant disease parasites makes this list doubly important to workers in this subject, and the Committee deserves the thanks of both research and advisory plant pathologists for providing such an up-to-date book of reference. There is no doubt that it will be welcomed by all concerned with plant diseases throughout the British Empire.

## FOOD HABITS

### The Origin of Food Habits

By H. D. Renner. Pp. 261. (London: Faber and Faber, Ltd., 1944.) 15*s*. net.

ALMOST the last habits anyone will give up are his food habits. So the average man is the despair of the dietitians and the Ministry of Food, who wish him to eat what is 'good for him' or what foods are available.

In the matter of food habits there are two sharply divided schools of thought: the one which we may call the 'Marie Lloyd school', which believes that food habits are based upon instinct and that what a man fancies does him good; and the other which considers all food habits conditioned reflexes due to upbringing. Most dietitians belong to the latter school. Any digestible substance which can provide calories, proteins, mineral elements and vitamins they call a food, whether the eater likes it or not. He can, they say, acquire a conditioned reflex for that food by practice, and quote illustrations from the War of 1914–18, when children brought up to eat margarine during the War refused butter when it became available after 1918. They also bring in observations made by explorers and anthropologists such as Stefánsson[1] and Margaret Mead[2]. The 'Marie Lloyd school' retort with Pavlov's own work on the psychic flow of gastric juice evoked by pleasant foods in dogs and the extension of Pavlov's work to man by Carlson. Moreover, there is Carl Richter[3], who has brought evidence to bear that Baltimore children behave towards cod liver oil as if guided by need rather than by conditioned reflexes.

The book under review collects evidence which will be used by both schools. The writer, who is rather heavily Teutonic in his handling of the problem, puts his emphasis on experimental psychology. For example, he thinks that people who are fond of food gobble it because they do not want to fatigue the sensory organs, and that when a food "goes round and round" in the mouth it is because the eater wishes to fatigue his gustatory apparatus for the unwanted food, so that he can swallow it without nausea. Surely simpler physiological explanations will cover both cases?

Though there is much in this book which every person interested in food, whether from gastronomic or dietetic reasons, will disagree with, it is one which every such person should read. It is difficult to sum up its attributes, and perhaps the best way to describe it is to borrow what Dr. Johnson is supposed to have said of the haggis: it is fine confused feeding.

## PROF. THE SVEDBERG

### The Svedberg, 1884–1944

Pp. 732. (Uppsala: Almquist and Wiksells Boktryckeri A.-B., 1944.) n.p.

IN universities, as in other walks of life, the personal expression of gratitude and appreciation is a rare event, and the means and opportunities of expression both difficult and infrequent. This volume was compiled by colleagues, friends and pupils to celebrate the sixtieth birthday of The Svedberg. If the limitation of war had not been imposed on the compilation, contributions would certainly have come in from all parts of the world.

Svedberg's original work lay in the field of colloid chemistry; but in 1923, as a result of a visit to Wisconsin, his interests were aroused in the possibilities of an ultra-centrifuge. While it is the development of this as an instrument of precision that gained for Svedberg his international reputation as well as a Nobel prize, his interests and activities are in fact much wider. Although he is by title professor of physical chemistry, it is significant that no less than thirty-one of the fifty-six communications in this volume lie in the field of what may now be termed biophysics. Another significant trend emerges in studying this volume—one which doubtless has been accentuated by the War, but which is a real part of the activities of the Institute—namely, the part played by Svedberg and his colleagues in the national economy of Sweden by co-operation with industries to the great advantage both of science and technology.

The volume contains a brief account of the Institute of Physical Chemistry at Uppsala, together with a number of original papers from the various departments of the University. Communications from other universities and high schools, notably the University of Lund, as well as from industrial laboratories are included. The topics dealt with cover a wide field of chemistry and biology, several of them naturally dealing with supercentrifugical, optical and electrophoretic measurements of biological material.

This collection of papers may be regarded as a cross-section of Swedish activities in chemical research during the war period, and any country might well be proud of such work and of The Svedberg, whose influence in and beyond the confines of Sweden has been so profound.

Eric K. Rideal.

# AN INTERNATIONAL SCIENCE CO-OPERATION SERVICE

By DR. JOSEPH NEEDHAM, F.R.S.

ON the occasion of the recent meeting of the Royal Society in India, and the admission of several Indian fellows, Mr. Winston Churchill sent a message which included the following words: "It is the great tragedy of our time that the fruits of science should, by a monstrous perversion, have been turned on so vast a scale to evil ends. But that is no fault of science. Science has given to this generation the means of unlimited disaster or of unlimited progress. When this War is won we shall have averted disaster. There will remain the greater task of directing knowledge lastingly towards the purposes of peace and human good. In this task the scientists of the world, united by the bond of a single purpose which over-rides all bounds of race and language, can play a leading and inspiring part"[1].

When, however, we come to the concrete necessity of implementing these truths, we see everywhere a growing conviction that after the War a much higher degree of international science co-operation must be attained. There are many who believe that the time has gone by when enough can be done by men of science working as individuals, or even in groups organized in universities or societies, within individual countries, and contacting each other as individuals, across national boundaries. Science and technology are now playing, and will in the future increasingly play, so predominant a part in all human civilization, that some means whereby science can effectually transcend national boundaries is urgently necessary. The various science co-operation offices which have already been set up under the stress of war in the capitals of the United Nations constitute a piece of machinery too precious to be allowed to disappear after the War.

The fundamental need for more intimate scientific contact among the nations might conceivably be met by a system of scientific attachés at the various embassies; but this might be found to harness the free movement of science in too much diplomatic formality. It is more likely to be partly met by sending from one country to another industrial scientists with loyalties limited to particular commercial interests; but this is very unsatisfactory, for their advice is unlikely to be truly unbiased and disinterested. What many of us would like to see would be an international science co-operation service, the representatives of which in all lands would have diplomatic status (or whatever status was accorded formerly to League of Nations officials) and full governmental facilities in communication and transportation, but who would be drawn from both government and academic laboratories, and hence would be free from commercial entanglements. One of the immediate aims of such an international service would be the conveyance of the most advanced applied and pure science from the highly industrialized Western countries to the less highly industrialized Eastern ones, though this is not to say that there would be no scope for westbound traffic too. In what follows, these ideas will be more fully worked out and concrete proposals made.

## Existing Machinery

Many recent recommendations (for example, the Beveridge Report, the Unilever paper on unemployment, the Nuffield College Statement, and the Report of the League's Delegation on Economic Depressions[2]) have laid great emphasis on the desirability of utilizing whatever is possible among the international agencies established to further co-operation during the War. It is generally recognized that the similar organizations which grew up during the War of 1914–18 were scrapped much too lightheartedly in 1918.

At the present time, then, a number of offices have been established to further scientific co-operation. Working trans-Atlantically are the British Central Scientific Office in Washington, maintained by the British Ministries of Supply, Production and other British organizations; and the American Scientific Office in London, mainly connected with the Office of Scientific Research and Development. Through these two offices, an enormous amount of information, of first-class war importance, has passed. As between Great Britain and the Soviet Union, apart from the detailed co-operation of war technologists and important visits of specific missions, such as the Surgical and the Chemotherapeutical Missions, there is in London an Anglo-Soviet Science Collaboration Committee, with which Sir John Russell has been prominently associated.

In view of China's relative backwardness in the industrial and technological field, it was natural that scientific co-operation between Chungking and the other United Nations' capitals should have been rather slow in getting under way, but since the early part of 1942 a Sino-British Science Co-operation Office (British Council Scientific Office in China) has been working very actively there. Since this Office has been under my charge, and since its working, in spite of exceptionally severe difficulties, both material and linguistic, helps to indicate the kind of thing that a science co-operation office may do, a short description of it may be given.

The Sino-British Science Co-operation Office (British Council Scientific Office in China) is financed by the British Council (for cultural relations with other countries), but was also accepted into an organic relation with the Chinese Government through the Council for the Promotion of Science in the National Defence, which has the status of a sub-committee of the Executive Yuan. It has, at present, a staff of seven scientific men and women, four British, two Chinese and one Indian. Its head works closely with the British Ambassador and the Ministers of all departments of the Chinese Government concerned with science and technology. In matters of pure science he is in continuous contact with the Science Division of the British Council, and in matters of applied and war science with a China office in the British Ministry of Production.

The work of the Office is divided into three aspects, which may be called respectively contact, supply and output. Under the first, a channel is available whereby Chinese Departments, such as those of Health, Mining, Ordnance or Agriculture, can maintain contact with the corresponding organizations or any other agencies desired in London or Washington (in the latter case through the British Central Scientific Office there). Help is also made available from India, as, for example, in the printing of maps for the Chinese Geological Survey, or the provision of a list of edible and poisonous plants in North Burma and the Shan States for the Chinese Surgeon-General. All such dependence on India as the forward base for Chinese science and technology involves careful maintenance of contact.

In the field of supply the great task has been to do something towards breaking the blockade of China's scientific life after the planned destruction of her laboratories by the Japanese and their re-establishment in the non-industrial hinterland. The Office is available to supply, and has supplied in very substantial amounts: (*a*) already existing information on any question in either pure or applied science, (*b*) ideas and proposals from the West to meet specific problems arising in China, (*c*) scientific literature in all branches, including books, typescripts, offprints, microfilmed journals, microfilm reading-machines, etc., (*d*) actual essential research apparatus, instruments and chemicals. At the time of writing, some five hundred important scientific books have already reached China and some two thousand more are on the way; those from Great Britain are supplied on a kind of 'lend-lease' principle; but the Office also secures American scientific books when asked for. Nearly a hundred crates of scientific apparatus have arrived, for Government as well as university laboratories and for applied as well as for pure research.

In the field of output, the Office sends to the West (*a*) manuscript papers by Chinese men of science for publication, (*b*) current Chinese publications in science, (*c*) abstracts of Chinese work in Western languages, (*d*) articles and résumés describing the work of Chinese scientific workers and technologists, etc. The field of output is naturally smaller than that of supply, since even before an exhausting ten years of warfare China was not highly developed technically and scientifically; but even in questions of technical aid the Chinese have been not only willing but also able to help their Western Allies, as the examples of the use of bamboo in aeroplane construction, and the preparation of quartz crystals for stabilizing radio frequencies, may bear witness.

In addition to all this work, the Office is able to advise Chinese technical departments from time to time, and to give assistance to the Chinese Ministry of Education with problems of the sending of scientific personnel to the West for study.

The work of the Office has complemented in a fortunate way that of the technical experts sent to China by the Cultural Division of the American State Department. These experts, of whom some twenty-five have visited China during the past year and a half, and whose work has been in general markedly successful, have been attached to the relevant Chinese Ministries and have worked entirely, as it were, in the field. Such a system of procedure lacks a central clearing-house through which requests for scientific information and aid can be co-ordinated. The British Office, which has throughout maintained close contact with the American experts, has been able to fill this need.

It may be said that the functions of Science Co-operation Offices are largely of a 'post-office' character. There is some truth in this. The Chungking Office, in particular, has had the task of assuring contact between Chinese and Western men of science and technologists in circumstances of special difficulty, including a blockade such that communication with the outside world is only possible by air. In post-war conditions, with the resumption of normal mail communications and the disappearance of censorships, the purely post-office work of such a bureau must necessarily be expected to decrease. The post-office aspect of a Science Co-operation Bureau, however, is really only a part of its work. In order to be successful it must spontaneously collect and disseminate scientific information. Without being able to answer all scientific queries themselves, its staff must know where the answers can be obtained. They must familiarize themselves with the conditions of scientific and technical life and thought in the country where they are stationed. They must have the confidence of the resident diplomatic personnel and be able to advise them authoritatively on problems relating to science and technology. They must be unfailingly at the service of the ministers of the Government Departments concerned with science.

Even for peace-time, however, the post-office aspect of such agencies is not to be despised. In all ages, exceptional scholars have acted as clearing-houses for science and learning, and the more so the worse the political chaos of the age. In the Middle Ages the monastic houses and the Arabic translators in Spain fulfilled such functions, or the Sung Confucians in China, or, in the seventeenth century, the tireless Comenius (Bishop Komensky). Exiled from his native Bohemia, Komensky kept together through years of wanderings not only his Church, the *Unitas Fratum*, but also the band of adherents of the "new, or experimental", philosophy, whose later great achievement was the foundation of the Royal Society, suggested by Komensky himself. And when the Royal Society was founded, what a post-office did Oldenburg, its first foreign secretary, keep! He it was who opened the series of letters from the microscopist, Leeuwenhoek, in which for the first time the new world lying beyond the limits of ordinary vision was described. A scientific post-office, indeed, requires the qualities of a "department of insufficient addresses", for its aim should be to ensure that a communication reaches its proper destination, a destination that the author himself may only vaguely know.

It was said above that Science Co-operation Offices should be in a position to give unbiased advice to Governments. It was also said in the preamble that they should aid in conveying the most up-to-date science and technology from the industrially advanced Western countries to the less-advanced Eastern ones. Here is a machinery for assisting the Eastern Governments, under strictly international auspices, with genuinely unbiased and disinterested information on their problems of industrialization. It would be a substantial improvement on the scramble of advisers with relatively narrow loyalties which is otherwise only too likely to be seen.

Besides the Washington, London and Chungking offices which have already been mentioned, steps have recently been taken in London towards a much higher degree of scientific co-operation among the constituent States of the British Commonwealth than heretofore. The British Commonwealth Science Committee was set up under the chairmanship of the President of the Royal Society in October 1941 in order to secure scientific co-operation in tackling the emergency problems of the immediate post-war period, to ensure that the most should be made of common scientific resources for improving scientific knowledge and the life of the people throughout the Commonwealth, and to consider means of promoting research co-operation in pure and applied science. In an Indian article[3], Prof. A. V. Hill wrote: "The British Commonwealth Science Committee has suggested the desirability of maintaining permanent scientific and technical representation in London and possibly *also in other capital cities of the English-speak-*

*ing world*. It is further of the opinion that if scientific and technical representatives of the Dominions and India are permanently established in London, these, together with official representatives of science in the United Kingdom and the Colonies, should be constituted into a British Commonwealth Science Collaboration Committee, to act with the Royal Society in the discussion of topics of common interest, to keep in touch with all agencies for the collection and dissemination of scientific information, to further schemes for co-operation in research and to make such recommendations and proposals for common action as seem fit"[3]. Prof. Hill went on to express the hope that such co-operation would lead in due course to a more general collaboration.

The interim committee's report has been published[4]. Its discussions so far seem to have centred mostly on the extension and rationalization of the existing means of broadcasting scientific information (for example, the abstracts journals), on research collaboration schemes, and on schemes for facilitating readier movement of scientific men from one country to another. But the extension of such schemes to the United States has been discussed. The interim committee has stressed that the implications of the Atlantic Charter point inevitably to the need for closer political, social and technical collaboration with the United States, the U.S.S.R., China and other countries or regions, such as Africa. It has accordingly expressed its hope that arrangements will be made to seek the co-operation, so far as may be practicable and appropriate, of scientific and technical representatives of *the United States, the Soviet Union, China and other countries outside the British Commonwealth*, permanently established in London. The editorial in *Nature* goes on to say that "the wisdom of this last recommendation is so patent that the support of all scientific workers is assured", but urges that concrete support should be manifested by scientific men through their professional organizations. This has no doubt since been done.

The foregoing remarks will have sufficed to show that the nucleus of a British Commonwealth Science Co-operation Service has been forming in London for some time past. Since it would lack, by itself, the vigour and influence of a truly international organization, its sponsors are clearly willing and anxious to enter such an organization if it can be brought into being.

At this point the question arises as to what would be the relationship of an International Science Co-operation Service to the activities of the scientific divisions of such organizations as the British Council and the Cultural Division of the American State Department. There certainly need be no conflict. Such organizations exist to demonstrate the cultural goodwill of their respective States towards the countries receiving the scholars and experts they send, and to bring to the notice of these other countries the scientific achievements of their past, in which they take a legitimate pride. The International Service would only have to keep in close contact with all such activities.

## Existing International Bodies

For the success of an International Science Co-operation Service, it would be essential that it should come under the aegis of whatever instrument of world organization the United Nations agree to set up at the end of the War. No doubt this will be centred on the 'big four' among the Allied Powers.

The International Science Co-operation Service could thus take its place among a number of international organizations, some with broad frames of reference, others with more restricted ones, which exist already or are in process of formation. The International Health Organization and the International Labour Office, two of the most successful agencies of the League, have never died, and are now in process of re-organization. The status of the International Institute of Intellectual Co-operation seems at present indeterminate. The International Institute of Agriculture, the World Power Conference, and the International Locust Control Commission, would all, it is believed, need little or no reviving.

Among the new organizations, the United Nations Relief and Rehabilitation Administration is at present most in the public eye; but the Food Conference at Hot Springs[5] ordered the creation of an Interim Commission on Food and Agriculture which is now drawing up plans for a permanent Commission for submission to the United Nations. All such organizations must be expected to have a good deal of concern with scientific research as applied to nutrition, agronomy, etc. The International Science Co-operation Service would have to keep in close touch with that side of their activities, and since its scientific frame of reference would be broader, would probably be able to offer them considerable help. It would be expected to outlast some of them, however, such as U.N.R.R.A., the existence of which has always been regarded as probably limited.

## Current Trends

To-day one has only to open any book or paper dealing with world affairs in any relation to science and technology to find writers expressing views closely related to those here put forward. Thus Prof. D. Mitrany, in a paper recently issued by the Royal Institute of International Affairs[6], argues for what he calls the 'functional' development of international organization. International government should be organized along the line of services to meet specific ends and needs. "A different complexion would be put on the problem of security if frontier lines became overlaid with a natural growth of common activities and common administrative agencies. Moreover, functional organization offers some prospect of mitigating the difficulties which arise out of State claims to equality by evolving arrangements which show a measurable and acceptable relation between authority and responsibility, relating authority not to sheer power but to the weight of responsibility carried by the several members." Precedents here are the European Danube Commission, the North Atlantic International Ice Patrol, the North Sea International Fisheries Board and the International Astronomical Union, so important for navigation. New organizations which should on no account be scrapped are the Combined Production and Resources Board, the Combined Raw Materials Board and perhaps the Allied Supplies Executive Secretariat. An International Science Co-operation Service has not yet originated; but no field could be more suitable than science for such a type of organization.

Allied to such conceptions is that of Dr. Arnold Raestad's International Centre of Scientific Information[7]. This proposal, however, relates rather to the

extremely important subject of popular education in science. Such a centre would be continually receiving and digesting reports of scientific progress throughout the world, and producing data suitable for elaboration by the journalist, the radio speaker, the film producer and the organizer of exhibitions. It would be a projection on a world scale of agencies such as the successful American Science News Service. It might ultimately be very suitably associated with the International Science Co-operation Service.

Allied also is the proposal of the British Association's Committee on Post-War University Education that some kind of world council of universities should be set up, sponsored perhaps by the Association of Professors and Lecturers of Allied Countries in Great Britain, and the Conference of Allied Ministers of Education[8].

In quite another sphere, the changing face of the modern world has necessitated proposals for the reform of the British Foreign Service[9]. Attachés and counsellors trained in economics are expected to play a greater part in embassies after the War than hitherto. The question has often been raised whether men with a scientific training should not also be included on embassy staffs. It was debated in Parliament in July 1943[10] and the proposal strongly recommended by Lord Samuel. In the course of the discussion great emphasis was laid on the Government's post-war plan for science, including arrangements for consultation and co-operation with the Dominions and the other United Nations.

Lastly, with regard specifically to West and East, Sir Henry Dale, in his message to the President of the Indian Science Congress Association[11], said: "There is a general desire among men of science in Britain for more intimate collaboration with those in India who are working for the advancement of knowledge in the same fields of research". Similarly, Minister Chu Chia-Hua, president of Academia Sinica, thanking the foreign secretary of the Royal Society, Sir Henry Tizard, for the gift of a facsimile of the Charter Book, wrote: "We believe it is our task to help to evolve and carry into practice some guiding principles of rational education for the world as a whole. Our first step in that direction must be to encourage and start widespread intellectual cross-fertilization. The Sino-British Science Co-operation Office has already done much in that direction in this country, and we hope that it may form part one day, in the not too far distant future, of an Office of World Science Co-operation. Compared with the Royal Society, the Academia Sinica is young, and not only in age; but as an organization of intellectual pursuit, we pledge to contribute our 'widow's mite' to the general wealth and strength that will some day bring about the supremacy of the intellect and reason". This interest on the part of the Chinese in the establishment of international organization appears again in the summary of proposals issued by the Commission for the Study of Post-war World Peace, of the Chinese People's Foreign Relations Association[12]. The summary stresses the importance of "international cultural and social co-operation". It is suggested that a cultural co-operation committee be established to undertake the work of changing the mentality of the people of the aggressor nations, and of strengthening cultural contacts. As regards social co-operation, the International Labour Office should extend its activities, including the improvement of social welfare and public health administration.

## Proposals

For the purpose of discussion, the following concrete proposals emerge from the arguments of this memorandum. It is proposed:

(1) That an International Science Co-operation Service should be set up by the United Nations at the conclusion of the War under the aegis of whatever supreme international organization is devised, parallel with the International Labour Office, the International (Permanent) Commission on Food and Agriculture, and other similar bodies.

(2) That the functions of the International Science Co-operation Service should be (*a*) the promotion of scientific co-operation in all its aspects, (*b*) the collection and dissemination of scientific information, (*c*) the furtherance of schemes of collaboration in research, (*d*) the facilitation of the movement of scientific men across national boundaries, (*e*) the provision of advice on scientific matters to government and diplomatic personnel of individual States when desired, (*f*) the provision of scientific assistance to all other international organizations.

(3) That the International Science Co-operation Service be supported by funds, which relatively to those required for other purposes would, of course, be small, subscribed by the Governments of the United Nations on some agreed income-tax basis.

(4) That the International Science Co-operation Service should have permanent representatives in all countries or regions, with diplomatic or 'League-official' status, and guaranteed Governmental facilities for communication and transportation.

(5) That the International Science Co-operation Service should have permanent headquarters in some centre to be later decided on; but that apart from a central and peripheral permanent secretariat, a considerable proportion of the total number of its officials should be working scientists of every nationality serving on a temporary leave-of-absence basis, that is, seconded from governmental, academic and possibly industrial, laboratories; in order to ensure that the organization shall always preserve the true atmosphere and understanding of research.

# WATER SUPPLY AND HEALTH

IN his Chadwick Lecture, delivered on October 3, on the "Treatment of Water in Peace and War", Lord Amulree gave a history of water supply, discussed its effect on the health of the community and described the various processes of purification which are applied to a water supply in order to render it epidemiologically safe and acceptable to the consumer, and the special precautions that have been taken during the War to protect it against war hazards.

Lord Amulree began by pointing out that water is one of the necessities of life, and stressed the

importance of ensuring its freedom from harmful impurities.

So long ago as 1832, during a cholera epidemic in Glasgow, the idea arose that the infection might have been carried by water. In this case Gorbals Parish furnished comparatively few cases of cholera, whereas in the rest of the city the epidemic was very severe. As Gorbals was provided with a soft water and the rest of Glasgow with a very hard one, the suggestion was made that the comparative freedom from cases in the Gorbals area was due to the soft water. Although this was by no means a full explanation, it was an important step forward in the epidemiology of cholera.

Next came the remarkable work of Dr. John Snow in connexion with epidemics of cholera in London in 1853 and 1854. At that time London was supplied by seven companies with water taken from the Thames and Lee and in many cases not filtered. One area was supplied by two companies, the Southwark and Vauxhall Water Company and the Lambeth Water Company, and by painstaking investigation Snow showed that whereas in the houses supplied by the Southwark and Vauxhall Water Company there were 286 deaths from cholera between July 8 and August 5, in those supplied by the Lambeth Water Company there were only 14 deaths. The former company derived its water from the Thames at Battersea, where contamination from London sewage was very heavy, whereas the Lambeth Company had, the previous year, moved its intake up to Ditton, which was free from such contamination. This convinced Snow that there was some connexion between the relative purity of the Lambeth Water Company's water and the low mortality from cholera of its consumers; but it was not until the following year, when another outbreak of cholera occurred in the neighbourhood of Broad Street, Golden Square, that he was able to provide definite proof that cholera was a water-borne disease. He found that nearly all the cases had drunk water from a pump in Broad Street, and at the end of the first week he persuaded the authorities to remove the handle of the pump so that it could not be used. As this was followed by a remarkable decrease in the number of cases of cholera, his proof was complete.

The observations of Snow have been amply confirmed since the discovery that bacteria were the causes of many diseases including cholera; but the interest lies in the fact that he reached the right conclusion by observation and deduction without any laboratory aid.

Typhoid fever is another of the great water-borne diseases. Prior to 1871, it was not differentiated in the Registrar General's returns from other diseases such as typhus and fevers of unknown origin, so that a true comparison cannot be made with what occurred in the first part of the nineteenth century; but these returns show a steady decline in the death-rate from typhoid fever from the five-year period 1871–75, when it was 374 per million living, to 4 in the last recorded period in 1936–40. "This," said Lord Amulree, "is a very remarkable and gratifying fall and must to a very large extent be attributed to a consciousness of the importance of water supplies to the public health of the country."

From what has been said, it is obvious that the most satisfactory kind of water supply is one that does not require any treatment and is drawn from an unpolluted source. Unfortunately, in a small and overcrowded island like Great Britain, it is difficult to find sufficient uncontaminated sources to supply the whole country, and many sources which in the past may have been quite wholesome have, by changing conditions, become liable to pollution.

Lord Amulree gave a warning that too much reliance should not be placed on bacteriological examination of the water, but that results obtained should be checked and used as a guide in investigating the possible sources of pollution. A word of warning was also given about the meaning of an unsatisfactory bacteriological analysis. Such a report does not necessarily mean that the whole of the consumers are immediately to be plunged into a large and serious epidemic. The presence of *Bact. coli* in the water means that the supply is liable to pollution, and that it is therefore possible that dangerous pathogenic organisms may at any moment gain access to the supply. Immediate steps should be taken to discover and remove or exclude the source of pollution, and at the same time special forms of treatment such as chlorination should be applied.

Unfortunately, a large number of water supplies in Great Britain come from rivers or other surface supplies. Rivers and streams are quite properly used in many places for the discharge of sewage effluents, and it must be remembered that no sewage treatment is aimed at making the effluent sterile, or even approaching a sterile condition, and for this reason treatment becomes necessary before the water is safe to be given to the consumers.

Proper treatment for water is complex and difficult, and requires supervision by expert staff who have laboratory facilities at their disposal. There are three stages of purification: storage, filtration and sterilization. In the early part of the twentieth century, Sir Alexander Houston, director of water examination at the Metropolitan Water Board, showed that polluted water is capable, to a very large degree, of purifying itself, if it be stored for long enough. Filtration may be done by slow or rapid sand filters. Sand filters act in two ways, by physical straining and by the biological destruction of the bacteria in the water by the saprophytic organisms in the 'skin' of the filter bed. Slow sand filters are worked at a rate of one to three million gallons per acre per day. Rapid filters work at much higher rates, and it is usual to add some chemical coagulant such as alumina to the water before filtration. Sterilization consists of adding chlorine or some other bactericide such as ozone to the water. Chlorine was first used as a sterilizer for a piped supply at Maidstone in 1897, following a serious outbreak of typhoid fever. It was extensively used by the armies in the field during the War of 1914–18 and has been widely employed since then, both in Great Britain and America, for treating water.

Like all measures which in modern times are hailed as panaceas, the treatment of water by chlorination has very definite limits. There is, for example, the danger of imparting an unpleasant taste to the water by an excess of chlorine, and there is also the fact that chlorine is only fully effective when applied to water which is free from any appreciable quantity of suspended organic matter. The adjustment of the dose to the varying condition of the water requires skilled supervision and laboratory control; it is a significant fact that of the water-borne outbreaks of typhoid fever which have occurred in recent years, most have taken place in areas where the water supply was supposed to have been treated with

chlorine. During the War, instructions were given to all water undertakings in Great Britain to chlorinate the water under their care. Lord Amulree said that this was done as a protection against sabotage by enemy agents, and has led to the erroneous idea that so long as a certain amount of chlorine is put into the water, the water is automatically safe for consumption and that very little or no care need be paid to other forms of treatment or to care of the source. This easy and fatal attitude of mind is one which it is going to be very difficult to eradicate. The fact that chlorination should be under skilled and intelligent supervision, with laboratory control, makes the process difficult to provide for in small rural supplies; hence it becomes more and more important for them to acquire a source free from pollution and to take steps to keep it so.

Some waters are corrosive to lead, and require treatment to protect the consumers from lead poisoning. This is due to the acidity of the water, and is usually corrected by the addition of lime.

Much discussion has taken place during the last hundred years on the relative merits of hard and soft water, and it has been contended that the use of a soft water not only results in a saving of soap but also that food cooked in soft water is more wholesome and more palatable, and that there is a saving in the wear and tear of garments washed in soft water. There are two processes used for water softening. One is based on the process evolved by Prof. Clark, and consists of adding lime to the water and precipitating the calcium bicarbonate as calcium carbonate. The other is called the base-exchange or zeolite method. When hard water is passed through a bed of natural zeolite or artificial base-exchange material, the sodium ions of the zeolite pass into the water and are replaced by the calcium and magnesium ions of the water which combine with the zeolite. By this means a completely softened water is obtained, and when the water issuing from the apparatus is no longer soft the material is regenerated by passing sodium chloride through it and thus reversing the exchange. In particular cases treatment has to be given for the removal of iron, which imparts an unpleasant taste to the water and stains clothing in the laundry. The treatment consists of aeration and sedimentation or filtration. Algæ which interfere with filtration and sometimes give rise to obnoxious tastes in the water may be controlled by treatment with copper sulphate or by coagulation.

Lord Amulree pointed out that the War has brought many new difficulties to water undertakings. In the first place, there was the establishment of camps and training grounds for troops, which led to the possibility of contamination of gathering grounds as well as the necessity for providing largely increased supplies of water. A further danger was the possibility of sabotage or the dropping of chemical or bacterial poisons into reservoirs from enemy aircraft. So far as is known, no attempt to poison water supplies has been made by the enemy.

The bombing of towns brought another danger, when water mains were broken in the same street as sewers. Owing to the great care that has been taken to isolate all sections of damaged mains and to sterilize them with chlorine after they have been repaired and before being put back to service, this danger has been successfully overcome.

DENISON B. BYLES.

# PROSPECTS OF CIVIL AVIATION

ON November 4 the Royal Aeronautical Society held at the Institution of Mechanical Engineers a discussion on civil aviation, and I agreed to preside. The time was appropriate in that a British Empire technical conference on the subject had just been held at Ottawa and one was going on on international aviation at Chicago. True, there is this difference in that, whereas agreement was required at the conferences, disagreement was required at the Royal Aeronautical Society's meeting in order to get real discussion.

The conduct of a meeting of this kind is always difficult: technicians are retiring, shy people as a rule, with the result that if you wait for someone to get up, it looks as if the meeting is slow, while if you call on people it appears to be pre-arranged and not spontaneous.

The canvas is very large that contains the picture of civil aviation, and it was certainly not our province to discuss any portion of it that brought in political prejudices or differences. How training or the economics of civil air transport comes within the ambit of a purely scientific society is not very clear, except on the basis that there is no one else to deal with it. I do not know whether a Saturday is a good day for such a gathering, starting at 10.30 a.m. and continuing until 6 p.m., but such was the demand to attend that tickets for admission were hard to come by and the place was full.

Brigadier-General Critchley, the director-general of British Overseas Airways Corporation, opened the discussion, speaking on training for civil purposes. He showed that much thought has been given to the subject. A pilot's career starts at twenty, for example; he must go anywhere until he is thirty-five, after which he can choose his route by virtue of his domestic ties until he is forty-five, when he comes off flying; but meanwhile he is to have training in administrative work, to see if he would be suitable for further employment in that line. It was interesting to note that one aircraft should average 3,000 hours a year and requires three crews to fly it. Accidents have been shown throughout the world to be at least 85 per cent pilot's errors.

Training for the R.A.F. and civil flying were said to be very different, a point disputed by Air Marshal Longmore as to engineers aboard. Altogether, chosen instrument or not, the personnel training of British Overseas Airways looked good, and General Critchley certainly impressed the meeting.

Major Thornton, a shipping director of Holts, an amateur flyer, a member of the Air Registration Board and a most treasured member of my Committee on Civil Aviation, dealt with the economics of flying, and startled everyone by saying he was surprised at being asked to speak on such a theme as the two subjects had never met! Coming from one who has dealt all his life with the running of tramp ships, his was a most enjoyable and instructive talk. He discussed frequency versus big machines, and showed a preference for frequency; but no one pointed out that the tiresome route London–New York non-stop compels at present a big machine on technical grounds. Major Thornton poured scorn, very rightly, on the aeroplane as a rival to ordinary freight carriers, but said it would create a new type of freight which is only of value if carried from place to place quickly.

Dr. Roxbee Cox pleaded for non-commercial routes

to be run to open up areas, an important side of this subject.

Sir Frederick Handley Page wanted to know if the jet would jump us from the speed of 200 m.p.h. to 300 m.p.h. without much difference in economy.

Mr. Peter Masefield made the curious point that 100 per cent load factor is uneconomical in view of the waste of money consumed in the organization necessary to reserve places, allot priorities, etc.; 60 per cent load factor, arrive and take your seat, would seem better! This particular subject is very large and requires and deserves much more attention than it got during a morning's discussion.

In the afternoon, Mr. Roy Chadwick, chief designer to A. V. Roe's of Manchester, who was responsible for the most remarkable of all bombers—the Lancaster—started the proceedings, but with war-time caution would only talk of conventional aircraft, whereas everyone, I believe, wanted to be done with them and dream of the next step. Along the lines of the conventional, however, he wanted a general purpose machine of about 100,000–150,000 lb. weight, 1,000 miles range, carrying thirty people, to cruise if needed at 300 m.p.h.

The great Hives followed him, the soul of Rolls Royce, and what a lot we owe to him for his own genius and the teams under him, unequalled in the world. He started by making the interesting point that whereas a locomotive does 100,000 miles between overhauls, an aero engine, although universally cursed, does 150,000 miles between overhauls. He would not admit that design for war engines is different from that of engines for civil use, except in minor points. He stressed the importance for maintenance of the whole power plant being interchangeable. Petter did not like this, but I do not think Hives meant that all power plants should be the same, as that would restrict design; but that in many machines you should be able to take out and replace the whole plant. Air Commodore Banks agreed that peace and war engines were similar.

Here I must state candidly that although both Chadwick's and Hives' contributions were most valuable and interesting, the fact that we are at war and unable for security reasons to speak of so much that is interesting, made the whole discussion rather flat; but that was not their fault.

Mr. Ogston pointed out that the cost of fuel for a year equalled the cost of the aeroplane. Hives countered with the *Queen Mary*, and worked it out in his head at more than half the cost a year!

Mr. C. G. Grey, comparing the difference in form of the Fortress and Liberator, which have identical performances, drew the startling deduction that both must be wrong and that aeronautics was not a science at all!

Mr. F. F. Crocombe put the size of a tail-less machine at 260,000 lb. before showing advantage over the conventional type. Wings, I suppose, get deep enough then to carry useful load and human beings. No trouble in landing gear in big machines was anticipated, the flexing of large spars not being mentioned.

Dr. Roxbee Cox described the jet engine well and pleaded for speed so as to get his engines to give more real horse-power. He was surprisingly optimistic on fuel consumption relative to ground covered, and I hope he is right.

Hives, in replying, admitted that Rolls Royce are in the jet business. He did not say whole-heartedly, but if this was not known before, some engine manufacturers will feel a cold douche down their backs.

Mr. W. P. Hildred, director general of civil aviation and another member of my Committee, spoke well and with great knowledge on route facilities. He put some difficult questions to us, such as what regularity of service is wanted; is ground organization spoiling pilots, what radio aids are really needed, etc., and even asked if aircraft should be self-navigating. It was noble of him to come along, bombarded and harassed as he was by the representatives at the conference in Chicago, asking for loads of information from his broad shoulders.

After tea—for the meeting went on until 6 p.m.—Mr. J. P. Jeffcock made the point that aircraft operators should compel the radio world to give them what they want rather than to take ready-made goods. After the War, radio aids should be on the ground, not all in the aircraft as war demands.

Sir Roy Fedden, president of the Royal Aeronautical Society, to whom the Society owes so much, was the last speaker, and told us what we had all realized, namely, that in spite of the hours spent, we had only touched the surface of many problems; and that once the conferences in the United States are finished, we are to have another day of discussion. The Society's secretary, Captain Pritchard, was expected to gasp, but in fact he suggested it, so in the New Year we shall be at it again.

BRABAZON OF TARA.

# NEWS and VIEWS

## Teaching and Research in Industrial Health

THE announcement by the Nuffield Trust of grants totalling £150,000 for teaching and research in industrial health is a reminder of the importance of this hitherto neglected aspect of the nation's well-being. In the early eighteenth century, Ramazzini, in his famous "Diseases of Tradesmen", emphasized the risks to health associated with certain occupations; yet it was not until the War of 1914–18 that official interest, apart from a few industrial hazards, was aroused in industrial health. In 1915 it was realized in Britain that munition workers suffering from ill-health were a serious liability to the safety of the country, since their absence affected production. The Health of Munition Workers' Committee, formed in 1915, found that few organizations kept health records, and that the need for preserving the health of those who work with hands or brain was but feebly recognized. Since 1918 progress has been made, and the recognition of the need for industrial medical officers, industrial nurses, welfare workers and labour managers has become more widely spread. It is, however, chiefly the firms with the best conditions who do the most to safeguard the health of their employees in all ways. There are numerous organizations still existing where health is nobody's concern. There are two aspects to be considered: (*a*) the need for systematic research into the actual incidence of sickness absence from various causes; (*b*) the means of expressing the results of this research in such a way that it can be applied easily. Before

the outbreak of the present War, much research had been done by the Industrial Health Research Board, but the results were only partially utilized.

Research in industrial health is not merely making an inquiry after something untoward has happened; yet this conception of research is found at times even in government departments. Research calls for much time and patient work, and should be done by people trained in its techniques. Then its initial application should be taken as seriously as the initial research: the attitude of mind of the research worker who prides himself on indifference to the application is out of place in these health problems. Finally, the results should be expressed not only for the research worker but also in a form that can be understood by people who are not specialists. In 1939, the lamentable lack of knowledge on the subject of industrial health had the same results as in 1914, though with less excuse. Medical men had little if any knowledge of the industrial conditions they were expected to understand. This should not be attributed to them as a fault, but as throwing into relief a defect in their training. We know that the total working environment, the social environment and the personalities of the people in authority, quite apart from home conditions, all play a part in determining the sickness absence of workers. It is therefore a definite move in the right direction that the trustees of the Nuffield Foundation have offered the Universities of Durham, Glasgow and Manchester, centres of large industrial populations, the financial means for the furtherance of teaching and research. It is also noteworthy that co-operation is suggested between the new departments and other departments such as science and engineering, the relevant Ministries and trades union officials, and the Industrial Health Research Board. Nor should research be limited to those technically called workers, that is, workers at the bench, but should include all those engaged in work of any kind. The grants, which are to be spread over a period of ten years, have been allocated as follows: £70,000 to the University of Manchester for a chair of industrial health; and £40,000 each to the Universities of Durham and Glasgow, at the former for the establishment of a new department under a university reader, and at the latter for a Sub-Department of Industrial Health in the present Department of Social Medicine.

## Joint Council of Professional Scientists

THE Joint Council of Professional Scientists was established for the period of the national emergency, to voice the collective opinion of qualified men of science. It was originally a joint committee of representatives of the Royal Institute of Chemistry and of the Institute of Physics, which was set up for the purpose of fostering co-ordinated action in matters of common interest, and was developed by the co-option of a botanist, a geologist, a mathematician and a zoologist, there being no corresponding professional bodies to represent those branches of science. One of the representatives of the Royal Institute of Chemistry is a metallurgist of similar standing. The Council has now been working for two years. Among matters which have received, or are receiving, its attention are the proposal to urge the Government to establish a central scientific and technical board; the Ministry of Labour's announcement regarding the minimum number of hours to be worked in laboratories and factories; the influence, on professional standards, of war-time university regulations governing the award of degrees; the conditions of service of professional men of science in the Colonial service; and the national policy regarding research and development work.

In June 1943 the Council was responsible for the issue of a statement on "The Place of Scientists in the Community". The views expressed were generally supported and given wide publicity, in the lay and technical Press, not only in Great Britain but also abroad. The Council has specially concerned itself with the resettlement of professionally qualified men of science after the War and with the various proposals which have been put forward for the proper utilization of their services. At the invitation of the Ministry of Labour and National Service, representatives of the Council gave evidence before the Ministry's Committees on "Higher Appointments" and on "The Further Education and Training of Demobilized Persons". Through the Joint Council, also, the Royal Institute of Chemistry and the Institute of Physics offered their continued co-operation with the Ministry in the resettlement period. The Council is also prepared to assist in the general resettlement of all who earn their living through their knowledge of any branch of natural science. Whether the Joint Council will continue in being when the national emergency no longer exists must depend on prevailing circumstances, and how far there may still be a need for professionally qualified men of science as such to voice their collective opinion on matters which concern the community in general, but especially themselves.

## Fuel and Power Advisory Council

A Fuel and Power Advisory Council has been constituted as follows: Sir Ernest Simon (*chairman*), Mr. Geoffrey Crowther, Sir John Greenly, Dr. E. S. Grumell, Sir Harold Hartley, Prof. C. N. Hinshelwood, Prof. John Jewkes, Viscount Ridley, Sir Robert Robinson, Mr. Geoffrey Summers and Mr. R. N. Quirk (*secretary*). The terms of reference are: "To consider and advise upon questions, referred from time to time by the Minister to the Council, concerning the development and utilization of the fuel and power resources of the country in the national interest."

## Higher Technical Education in Great Britain

IN a paper on "The Status of Higher Technical Education" published by the Association of Technical Institutions (Hon. Secretary, Loughborough College, Leics. 6*d*.), Dr. T. J. Drakeley, principal of the Northern Polytechnic, London, states that while on the Continent, "technical university studies are accorded the same status as university studies and both lead to the award of degrees, here, most of our best students, in fact most students have been discouraged from taking higher technical courses because of their apparent inferior nature"; consequently industry has received few trained men and has suffered the decline foretold by Lyon Playfair in 1852. Dr. Drakeley strenuously combats the foreign view (which is supported even by some British chemists) that "we do not possess the right temperament to maintain industrial progress", and claims that our ineffectiveness in the industrial field is due to our lack of appreciation of "the vast importance of technical training in the development of an industry—whereas we state that trade cannot be taught *within* a school, our foreign competitors realise that trade cannot be taught *without* a school".

In discussing the relation between the universities and technical colleges of Great Britain, Dr. Drakeley directs attention to the fact that some of our major technological studies are not recognized for the award of degrees, and he suggests four ways in which the British problems of higher technological education might be solved, namely: (1) by transferring all existing technological studies to the universities and inaugurating new degree courses; (2) by conferring university rank on the major technical colleges; (3) by creating a national technological university with existing major technical colleges as the core; and (4) by establishing a non-university institution awarding the equivalent of a degree (for example, a diploma in technology) in approved technical colleges. He appears to favour the fourth of these alternatives owing to the time factor involved; "we must raise the status of technical education to that of university education . . . immediately, not only for the students coming forward now to study a technology but for the men on return from the Services". Readers of *Nature* will recall that the problem was discussed in some detail in these columns towards the end of last year and again in *Nature* of June 3, 1944, p. 663.

## Skiagram

MR. W. McADAM ECCLES, consulting surgeon to St. Bartholomew's Hospital, London, has prepared a statement urging that an international effort should be made to agree on a standard term to be used for the photogram produced by X-rays. He quotes no less than nineteen words which have been used in connexion with "a negative produced upon a film sensitive to the action of X-rays". Chronologically they are:

1. X-ray.
2. X-rays.
3. X-ray picture.
4. X-ray photograph.
5. X-ray plate.
6. X-ray film.
7. Röntgen photograph.
8. Roentgenogram.
9. Actinograph.
10. Actinogram.
11. Radiograph.
12. Radiogram.
13. Sciagraph.
14. Sciagram.
15. Shadowgraph.
16. Shadowgram.
17. Skiogram.
18. Skiagraph.
19. Skiagram.

Mr. Eccles believes that two only of this collection of terms will bear scrutiny: they are 'skiagram' and 'X-ray film'. The latter is dismissed as being cumbersome and because one of the words used has alternative meanings. On the other hand, skiagram is etymologically sound (from the Greek 'skia' a shadow, and 'gramma' writing). It implies a 'shadow writing', which is a negative produced by X-rays. For some time it has been used in the scientific meaning, and it has never been used for any other purpose. Mr. Eccles therefore urges that the word 'skiagram' should be officially adopted as the standard term, so that it would be generally used in text-books, courts-of-law, medical reports, etc.

This is, of course, not the first time that reference has been made to the slipshod use of scientific terms generally and to the anomalies arising from the word 'radiogram' (see *Nature*, February 19, p. 218). The fundamental difficulty is that no body exists in Great Britain which is acknowledged as the authority on the use of scientific, or indeed other, words. Perhaps, indeed, it is foreign to the fluid character of the English language to accept direction in this manner. In the case of the word 'skiagram', however, with its relatively narrow field of use, it might well be considered by, say, the Physical Society, the British Institute of Radiology and the appropriate section of the Royal Society of Medicine, whether agreement might not be reached on the adequacy and appropriateness of the term, with the view of using it in these Societies' publications. Should it be adopted, no doubt its general acceptance would quickly follow.

## Mechanical Properties of Matter

Two recent papers (*Proc. I. Mech. E.*, 151, No. 2; 1944) deal with the properties of materials, and are of particular interest. "A Renaissance of Mechanical Properties", by Sq.-Leader A. C. Vivian, is a plea for clarity in the terms describing the mechanical properties of metals, and demonstrates the fallacy of calculating stresses on a nominal basis instead of actual cross-sectional areas. The fundamental relationship between the factors stress, strain, temperature and loading-rate is discussed in detail, and a system of symbols is suggested for defining exactly the various properties of metals. "The Significance of Tensile and other Mechanical Test Properties of Metals", by Dr. H. O. Neill, is a critical consideration of the conventional quantities obtained from the tensile test, dealing particularly with the measurement of work-hardening capacity and plasticity. Attention is given to the various methods of plotting the results of tensile tests which enable these properties to be evaluated, and numerical data are given. The discussions on both these papers are included.

## Earthquakes during July

DURING July 1944, twenty-seven earthquakes and earth tremors were registered by the seismographs at the observatory at Toledo, Spain. Those on July 17 (epicentral distance 112·5°), 19 (epicentral distance 119·1°), and 27 registered the greatest amplitudes at Toledo, whereas the shock on July 18 may have been a local tremor. At Wellington, New Zealand, during the same month, five strong shocks were registered. On July 10 the shock is thought to have originated south of the Kermedecs. On a basis of instrumental evidence received from thirteen other stations, the United States Coast and Geodetic Survey has estimated the epicentre of the shock of July 27 at 0h. 04·2m. G.M.T. to have been near 54·5° N., 166·5° W., which is in the Aleutian Islands, and the depth of focus to have been rather greater than normal. In New Zealand during July fourteen shocks were reported as having been felt. The greatest of these were of intensity 4 on the Modified Mercalli scale, and occurred on July 1 at Opotiki and Whakatane, and on July 11 at Karamea and Westport.

## American Telephone and Telegraph Co.: Fellowships

THE American Telephone and Telegraph Company has established a trust fund to finance post-doctorate fellowships in physical science in honour of Dr. Frank B. Jewett, president of the U.S. National Academy of Sciences and vice-president of the Company in charge of development and research, who has just retired, having reached the Company's retirement age. Five fellowships will be awarded annually. The object is to stimulate and assist research in the fundamental physical sciences, and particularly to provide the holders with opportunities for individual development as creative workers. The fellowships provide an annual honorarium of 3,000 dollars to the holder and 1,500 dollars to the institution at which the recipient elects to do research. The fellowships will enable their recipients to devote themselves to research in pure science for a year or two following their doctorates. Since the purpose is to provide

fungus or bacterial parasites the right-hand column gives the name of the causative agent, for example, mosaic virus, manganese deficiency, irregular water supply, etc. There is one important change in lay-out as compared with previous lists, this being the fact that the host plants instead of being arranged in groups, such as fruits, vegetables, etc., are now all placed in alphabetical order according to their names as ordinarily used. The result is that there is no need for a host-plant index.

In the case of the more important diseases which are also prevalent abroad, foreign common names from several countries are given in slightly smaller type under the selected British common names. There are an index of authors' names and abbreviations, one of the accepted scientific names of both host plants and parasites, and one of foreign common names of various diseases. Many readers will note and approve the separate index providing common names of diseases in Russian.

This attempt at uniformity in nomenclature of diseases is to be commended in a field where confusion is still too often met with. The fact that changes repeatedly occur in the scientific names of plant disease parasites makes this list doubly important to workers in this subject, and the Committee deserves the thanks of both research and advisory plant pathologists for providing such an up-to-date book of reference. There is no doubt that it will be welcomed by all concerned with plant diseases throughout the British Empire.

D. E. Green.

# FOOD HABITS

## The Origin of Food Habits

By H. D. Renner. Pp. 261. (London: Faber and Faber, Ltd., 1944.) 15*s.* net.

Almost the last habits anyone will give up are his food habits. So the average man is the despair of the dietitians and the Ministry of Food, who wish him to eat what is 'good for him' or what foods are available.

In the matter of food habits there are two sharply divided schools of thought: the one which we may call the 'Marie Lloyd school', which believes that food habits are based upon instinct and that what a man fancies does him good; and the other which considers all food habits conditioned reflexes due to upbringing. Most dietitians belong to the latter school. Any digestible substance which can provide calories, proteins, mineral elements and vitamins they call a food, whether the eater likes it or not. He can, they say, acquire a conditioned reflex for that food by practice, and quote illustrations from the War of 1914–18, when children brought up to eat margarine during the War refused butter when it became available after 1918. They also bring in observations made by explorers and anthropologists such as Stefánsson[1] and Margaret Mead[2]. The 'Marie Lloyd school' retort with Pavlov's own work on the psychic flow of gastric juice evoked by pleasant foods in dogs and the extension of Pavlov's work to man by Carlson. Moreover, there is Carl Richter[3], who has brought evidence to bear that Baltimore children behave towards cod liver oil as if guided by need rather than by conditioned reflexes.

The book under review collects evidence which will be used by both schools. The writer, who is rather heavily Teutonic in his handling of the problem, puts his emphasis on experimental psychology. For example, he thinks that people who are fond of food gobble it because they do not want to fatigue the sensory organs, and that when a food "goes round and round" in the mouth it is because the eater wishes to fatigue his gustatory apparatus for the unwanted food, so that he can swallow it without nausea. Surely simpler physiological explanations will cover both cases ?

Though there is much in this book which every person interested in food, whether from gastronomic or dietetic reasons, will disagree with, it is one which every such person should read. It is difficult to sum up its attributes, and perhaps the best way to describe it is to borrow what Dr. Johnson is supposed to have said of the haggis: it is fine confused feeding.

# PROF. THE SVEDBERG

## The Svedberg, 1884–1944

Pp. 732. (Uppsala: Almquist and Wiksells Boktryckeri A.-B., 1944.) n.p.

In universities, as in other walks of life, the personal expression of gratitude and appreciation is a rare event, and the means and opportunities of expression both difficult and infrequent. This volume was compiled by colleagues, friends and pupils to celebrate the sixtieth birthday of The Svedberg. If the limitation of war had not been imposed on the compilation, contributions would certainly have come in from all parts of the world.

Svedberg's original work lay in the field of colloid chemistry; but in 1923, as a result of a visit to Wisconsin, his interests were aroused in the possibilities of an ultra-centrifuge. While it is the development of this as an instrument of precision that gained for Svedberg his international reputation as well as a Nobel prize, his interests and activities are in fact much wider. Although he is by title professor of physical chemistry, it is significant that no less than thirty-one of the fifty-six communications in this volume lie in the field of what may now be termed biophysics. Another significant trend emerges in studying this volume—one which doubtless has been accentuated by the War, but which is a real part of the activities of the Institute—namely, the part played by Svedberg and his colleagues in the national economy of Sweden by co-operation with industries to the great advantage both of science and technology.

The volume contains a brief account of the Institute of Physical Chemistry at Uppsala, together with a number of original papers from the various departments of the University. Communications from other universities and high schools, notably the University of Lund, as well as from industrial laboratories are included. The topics dealt with cover a wide field of chemistry and biology, several of them naturally dealing with supercentrifugical, optical and electrophoretic measurements of biological material.

This collection of papers may be regarded as a cross-section of Swedish activities in chemical research during the war period, and any country might well be proud of such work and of The Svedberg, whose influence in and beyond the confines of Sweden has been so profound.

Eric K. Rideal.

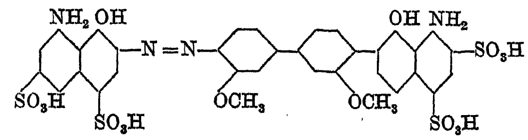
## Wharton's Jelly Considered as a Conducting Path

DURING the course of experiments conducted on the sheep fœtus, dyes were injected into the umbilical cord with the object of exploring movements of substances in the cord along non-vascular pathways. The dyes used were a dis-azo dye,



related to trypan blue, and the same dye linked to serum albumin by a diazo linkage. The dye, when linked to protein in this way, cannot dissociate from the albumin, and hence acts as a tag to the protein. These substances were prepared by one of us (P.D.M.).

Fœtuses of different age periods were delivered by Cæsarean section and kept alive, with the placental site intact, and the mother alive, for periods up to five hours. The fœtuses were not allowed to breathe. 2–5 ml. of the dye solution was injected under low pressure into Wharton's jelly (avoiding the main umbilical vessels) four to five inches from the abdominal wall of the fœtus. The injection occupied approximately one minute. The injection mass passed slowly along the cord into the abdomen of the fœtus. At the end of three hours, the blue colour of the dye was well marked throughout the whole substance of the cord on the fœtal side of the injection site, over the allantois, the upper portion of the bladder, the umbilical arteries and the adjacent peritoneal reflexions. No coloration was observed along the pathway to the liver or any other site. It is clear, therefore, that the dye did not find its way into either of the three other escape routes from the cord, namely, (1) the vascular system (there are small vessels in the Wharton's jelly of the sheep as was shown by Tait); (2) the allantoic duct, in which case the dye would have appeared in the bladder; (3) the extra embryonic cœlom leading to the *inside* of the peritoneal cavity.

It is therefore evident that molecules as large as serum albumin may pass from the cord into the embryo by a pathway which is functionally and embryologically distinct from routes (1), (2) and (3) above. The molecules of albumin move at a much greater rate than could be accounted for by diffusion. There must, therefore, under the conditions of these experiments, be a bulk flow of fluid from the cord into the embryo. As the pressure available cannot have been large, the resistance to flow through the connective tissue must be small.

Tait[1] reported results of injection into the cord which are different from the results we obtained. It is possible that the differences are due to his dyes being much more coarsely particulate than those used here.

The interest in the above observations lies in the fact that the Wharton's jelly in the umbilical cord of the sheep is continuous with similar material in the cotyledons of the placenta (Barcroft and Barron), implying a path from the placenta to the fœtus other than the purely vascular one. It has yet to be discovered whether material can pass in the fœtus further than the restricted area which we have described. Clearly, if there is a continuous flow of fluid, the water at least must do so, but what sized molecules it can take with it is another question.

Further research is required to ascertain how far this non-vascular pathway in the cord is of importance in the fœtus.

We are deeply indebted to Dr. D. V. Davies for his kind advice on the anatomical problems involved.

## Production of Gliotoxin by *Trichoderma viride*

GLIOTOXIN was first described by Weindling and Emerson[1] as a metabolic product of *Trichoderma lignorum* (Tode) Harz [= *T. viride* Pers. ex Fries]. Weindling afterwards[2], on the advice of C. Thom and M. Timonin, reported that he had described the fungus incorrectly, and that instead it should be identified as a *Gliocladium*, similar to *Gliocladium fimbriatum* Gilman and Abbott. I have found that strains of *Trichoderma viride* produce gliotoxin, and I suggest that it is extremely probable that the fungus used by Weindling was not *G. fimbriatum*, but was a *Trichoderma* as he originally supposed.

In 1942 I received from Prof. H. Raistrick a culture which had been supplied to him as Weindling's strain of *G. fimbriatum*. Using the culture medium recommended by Weindling and Emerson[1], I have found this to produce gliotoxin in 4-day still cultures at the rate of about 50 mgm. per litre. Afterwards, in the course of examination of a number of isolates of *T. viride*, one isolated from a local soil (No. 211) was found to possess marked powers of antagonism to a number of bacteria and fungi. This organism was then found to produce gliotoxin in yields of about 95 mgm. per litre, that is, at twice the rate of 'Weindling's strain' under similar conditions.

Analyses (Weiler and Strauss) of the products from both fungi agree with $C_{13}H_{14}N_2S_2O_4$ as found for gliotoxin by Dutcher[3], not with $C_{14}H_{16}N_2S_2O_4$ as originally suggested by Weindling and Emerson. Data are given in Table 1.

TABLE 1.

| % | Calc. for $C_{13}H_{14}N_2S_2O_4$ | Gliotoxin from Strain No. 211 | Gliotoxin from 'Weindling's strain' |
|---|---|---|---|
| C | 47·8 | 47·8 | 47·8 |
| H | 4·3 | 4·4 | 4·4 |
| S | 19·7 | 19·9 | 19·8 |
| N | 8·6 | 8·3 | 8·6 |

Until I discovered the production of gliotoxin by a fungus which I considered to be an obvious *Trichoderma*, I accepted the nomenclature of 'Weindling's strain' as *G. fimbriatum* Gilman and Abbott. Since these two fungi appeared very similar in macro-

scopic cultural characteristics, a more detailed examination of the two isolates was made. Apart from minor cultural differences, such as the relative amounts of sporulation on different media, the two were very similar morphologically. Fortunately, I was able at the same time to obtain another culture of *Gliocladium fimbriatum* Gilman and Abbott from the National Collection of Type Cultures (*NCTC.* No. 6599). This was clearly different from the two isolates mentioned above, and I have not been able to demonstrate the production of gliotoxin by this fungus. In Table 2 certain morphological features of these three fungi are compared with the original description of *G fimbriatum* by Gilman and Abbott[4].

TABLE 2.

| | *G. fimbriatum* (data from Gilman and Abbott[4]) | *G. fimbriatum. NCTC.* 6599 | *G. fimbriatum.* 'Weindling's strain' | *T. viride* No. 211 |
|---|---|---|---|---|
| Conidia | 6·5–9·5 × 2·5–4 μ | 5·5–7·5 × 3–3·5 μ | 4·4–5·2 × 3·5–4·5 μ | 4·5–5·5 × 3·5–4·5 μ |
| Phialides | 10–20 μ | 14–20 μ | 7–11 μ | 7–10 μ |
| Chlamydospores | Not recorded | None | Abundant | Abundant |

It will be seen that 'Weindling's strain' and my isolate of *T. viride* are similar, and that both differ from *G. fimbriatum* (*NCTC.* 6599) and from Gilman and Abbott's description of *G. fimbriatum* in having shorter phialides, smaller and less markedly elliptical conidia, and in possessing chlamydospores of a type invariably found in *Trichoderma*. The conidia of *G. fimbriatum* (*NCTC.* 6599) are borne in slime-balls on a polyverticillate penicillus typical of the genus, usually more complex than that figured by Gilman and Abbott. The spore-balls of 'Weindling's strain' and *T. viride* No. 211 are borne at times on single phialides, or on two to three phialides, arising from the conidiophores in a manner typical of *T. viride*, but a high proportion are borne on phialides arising from a group of branches or metulæ produced terminally on the conidiophores, giving a rather *Gliocladium*-like appearance. Nevertheless, the characters already mentioned, the formation of 'tufts' of conidiophores, the rapid growth, and general colony characteristics all point to 'Weindling's strain' and my isolate No. 211 being strains of *T. viride*. They are aberrant strains in so far as the formation of a rather complex conidiophore is concerned; but, as Bisby[5] has shown, *T. viride* exhibits considerable strain variation in several directions.

It seems clear, from the evidence given above, that the fungus obtained as Weindling's strain of *Gliocladium fimbriatum* is really a strain of *Trichoderma viride*. Moreover, Weindling[2] himself mentions that the conidia of his organism were smaller than those recorded for *G. fimbriatum* Gilman and Abbott, and that it produced chlamydospores similar to those of *Trichoderma*, which had not been recorded by Gilman and Abbott for *G. fimbriatum*.

Antagonism based on the production of antibiotics is probably of great importance in determining the balance between various micro-organisms in such habitats as soil. It seems probable that the well-known antagonistic powers of *T. viride* are due, at least in part, to the production of gliotoxin. The natural biological role of gliotoxin can now be regarded as much greater than was heretofore imagined, since *T. viride* is widespread and abundant in soil, unlike the relatively rare *G. fimbriatum*.

Thanks are due to Dr. G. R. Bisby for help in the nomenclature of some of the organisms studied, and to Mr. J. C. McGowan for the chemical identification of gliotoxin.

## Carcinogenic Effect of Aminoazobenzene

SINCE Kinosita[1] first showed that rats developed malignant tumours of the liver when fed a deficient diet containing N,N-dimethyl-*p*-aminoazobenzene (butter-yellow), much work has been done in an attempt to elucidate the mechanism whereby this azo-dye brings about neoplastic changes in liver tissue. One aspect studied has been the metabolism of the dye itself; Stevenson, Dobriner and Rhoads[2] were able to isolate *p*-aminophenol and *p*-phenylenediamine, and also their N-acetylation products, from the urine of rats receiving the dye orally. Thus the azo-link is split as in the case of *o*-aminoazotoluene[3] and other azo-compounds in the animal body. However, the absence of N,N-dimethyl-*p*-phenylenediamine from fractions prepared without addition of sodium hydrosulphite suggested that complete demethylation occurs at some stage prior to the acetylation of the *p*-phenylenediamine. This lability of the N-methyl groups has been neatly demonstrated by Jacobi and Baumann[4], who found butter-yellow could function like other methyl-donors in protecting young rats against kidney lesions when on a choline-free diet.

Jacobi and Baumann[4] also suggested that the protection afforded by high-protein and high-riboflavin diets against butter-yellow carcinogenesis was due, at least in part, to the demethylation of the dye to *p*-aminoazobenzene, which they quote Kinosita as stating is non-carcinogenic. Kensler, Dexter and Rhoads also state that "Aminoazobenzene . . . does not produce liver cancer in the rat". This would attribute to the methyl groups a dominant role in the process of carcinogenesis. However, the methyl groups in *o*-aminoazotoluene (which is more carcinogenic for mice than is butter-yellow[6]) are attached to carbon atoms and presumably are not labile. Hence, it seemed unlikely that the N-methyl groups of butter-yellow were so essential as these workers suggested, and that *p*-aminoazobenzene itself might really be carcinogenic.

Miller, Miner, Rusch and Baumann[7] evolved a low-protein basal diet which enabled them to induce hepatomas in 90–100 per cent of rats receiving a butter-yellow supplement for four months; the incidence on a full diet was only 80 per cent at eight months. A group of fifteen albino rats of Wistar origin were placed on a similar diet in this Department, except that starch was replaced by boiled potatoes as a war-time modification. This modified diet, supplemented with butter-yellow (0·06 per cent of diet), induced malignant liver tumours after seven months, that is, it caused no marked acceleration

in the production of tumours, compared with a full diet. However, sixteen similar rats have been fed on this modified diet, supplemented with *p*-aminoazobenzene (at first 300 mgm. per 100 gm. diet, and, later, 200 mgm. per 100 gm. diet), for more than eighteen months, so far. Of eight rats now dead, one (dying at thirteen months) had a few whitish spots visible to the naked eye, in the liver, and these proved on microscopic examination by Dr. P. R. Peacock to be small hepatomas. Two other rats died at seventeen months, both having very large tumours in one lobe and smaller tumours in the other lobes of the liver; in one case, the liver weight (including tumours) was 47·8 gm. These tumours were liver-cell carcinomas which were metastasizing via blood-vessels to the mesentery. It is hoped to publish, in conjunction with Dr. P. R. Peacock, a full account of the pathology of these lesions elsewhere; but it may now be said that *p*-aminoazobenzene is carcinogenic for rats fed the dye in a somewhat restricted diet for a long time.

This finding is in accordance with the results obtained by Kensler *et al.*[5,8] and Potter[9], who found various enzyme systems to be inhibited by the *p*-diamines which are liberated from butter-yellow and related azo-dyes when the azo-link is reduced. Thus N,N-dimethyl-*p*-phenylenediamine caused 64 per cent inhibition of urease at a molarity of $1 \times 10^{-3}$. *p*-Phenylenediamine at the same concentration caused 45 per cent inhibition[9]. Similarly, in the cases of succinoxidase, yeast carboxylase and coenzyme-I, *p*-phenylenediamine caused a significant degree of inhibition. If this effect on enzymes plays a part in the process of liver carcinogenesis, then it would be reasonable to expect that aminoazobenzene would be carcinogenic, though less so than the fully methylated compound. This is what we have found to be the case. It is, moreover, clear that the butter-yellow split-product must have its effect prior to the demethylation process, that is, reduction of the azo-link must precede demethylation; otherwise the two dyes would eventually yield the same split-product, *p*-phenylenediamine, and have the same degree of carcinogenic power.

## Taste of Thiouracil and Phenylthiocarbamide

TWELVE years ago, Fox[1] discovered a curious property of phenylthiocarbamide. He was putting some of the substance into a bottle when a colleague complained of the extremely bitter taste, which Fox himself was unable to confirm. The question was investigated by Blakeslee[2], who found that a sample of the American population contained 40 per cent of individuals who were non-tasters. Furthermore, it was found that if two non-tasters married, their children were also non-tasters. The ability to taste ($T$) is dominant to non-tasting ($t$), so that parents having the constitution $Tt$ may have non-tasting children; but if one of them is homozygous, $TT$, then all the children will be tasters of phenylthiocarbamide. The test has been used as a genetic marker in the investigation of human pedigrees[3,4,5].

As the chemical constitution of thiouracil and phenylthiocarbamide indicate a common origin, it was considered desirable to investigate the taste of the former. Sixty volunteers submitted to the tests. Approximately one half of a 0·2 gm. tablet of thiouracil was chewed, and the subject was asked to state what taste it had. The responses varied from intensely bitter to a chalky taste, but there was no difficulty in identifying the tasters from the non-tasters. A solution of phenylthiocarbamide was prepared containing 0·005 per cent, and the subjects were given a teaspoonful each. This solution divided the group into two, tasters and non-tasters, in the same manner as the thiouracil, with one exception. This was a male who considered that thiouracil was intensely bitter, but was unable to taste 0·005 per cent phenylthiocarbamide although a 0·01 per cent solution was tasted. He was considered to be a taster.

| | Tasters | Non-tasters | Total |
|---|---|---|---|
| Males | 23 | 10 | 33 |
| Females | 20 | 7 | 27 |
| Total | 43 | 17 | 60 |

The proportion of tasters to non-tasters is shown in the accompanying table. The numbers were too small to establish the excess of non-tasting males which is known to occur. The material included a female taster who had a non-tasting husband. They have two children, a non-tasting boy and a tasting girl. It follows that the woman is probably heterozygous ($Tt$) for the factor concerned in controlling the taste of both thiouracil and phenylthiocarbamide. Two identical twins were both tasters.

It would appear that the ability to taste thiouracil is inherited in the same manner as that of phenylthiocarbamide. A few subjects taking thiouracil therapeutically showed nothing to suggest that their response differed in any way from the majority. So far as our knowledge goes, this peculiar property has only genetic significance.

## Apparent Vitamin C as a Possible Precursor of True Vitamin C in Walnuts

UNRIPE walnuts have previously been reported[1,2] to contain considerable amounts of apparent vitamin C, the provisional term suggested[3] for substances which so closely resemble true vitamin C in chemical and physical properties that they may be confused with the latter when it is being estimated by the usual dye titration method, though they may be distinguished from it by modifications[4,5] of Lugg's

formaldehyde method[6]. A detailed study (on some hundreds of samples) has now been made of the relative proportions of true and apparent vitamin C in different tissues of the walnut throughout the period of growth and ripening.

The fruit in the earliest stages may contain practically no true vitamin C but very high concentrations (more than 1,000 mgm. per 100 gm.) of apparent vitamin C. As growth and maturation proceed, the proportion of true vitamin C in the total vitamin C gradually increases until in the nearly ripe nuts it approaches 100 per cent. An explanation is thus provided of the lower proportions of apparent vitamin C found by other workers[4,7,8] who examined more mature nuts. Moreover, the apparent vitamin C also occurs in high concentration in buds and leaves, and the concentration gradients suggest that a steady flow occurs from these centres of photosynthetic activity to the tissues of the nut in which it may be converted into true vitamin C. The most striking results have been obtained with samples of *Juglans regia*. With *J. nigra* the results were similar but less marked, and with *J. rupestris* and *Carya ovalis* var. *obcordata* the part played by apparent vitamin C is more obscure. This season no specimens were available of *J. cinerea*, in which we found last year that 73 per cent of the total vitamin C was apparent vitamin C.

Our results in the 1943 season had already indicated the possibility that apparent vitamin C might be a precursor of true vitamin C in walnuts[9], and our results in 1944 have provided further evidence in favour of this hypothesis. Attempts to establish the identity of the apparent vitamin C in walnuts are meeting with certain difficulties, and until these are overcome it appears premature to discuss various interesting possibilities arising from our findings. However, we think it desirable to publish this preliminary note and thus afford other workers the opportunity of checking our results.

The possible presence in apples of a vitamin C precursor has recently been mentioned by West and Zilva[10] when describing the results of several years work in which clear evidence was obtained that the true vitamin C content may increase during storage. It would be of interest to discover whether their apples contain any apparent vitamin C and, if so, whether the proportion of this decreased as the proportion of true vitamin C increased, as should occur if the former is a precursor of the latter. Unripe walnuts do not withstand storage so readily as apples do, and we have not yet been able to duplicate with our walnuts West and Zilva's lengthy storage experiments on apples. Over short periods (of a few weeks) we have obtained evidence with walnuts of decreases in the concentration of apparent vitamin C in parallel with increases in concentration of true vitamin C which were of the order to be expected from West and Zilva's results; but so far there has not been a high degree of significance in the differences observed.

Whether further work succeeds or fails in proving apparent vitamin C to be a precursor of true vitamin C, there already seems to be clear evidence that, in walnuts at least, apparent vitamin C is not a mere degradation product such as might be formed during the processing of foods, but rather a substance playing an important part in plant metabolism. The question of the part, if any, which it plays in animal metabolism, and of its possible physiological activity, has still to be decided.

We are indebted to Dr. E. J. Salisbury, director of the Royal Botanic Gardens, Kew, for material, to Prof. R. A. Morton for advice and for spectrographic examination of our extracts, to Dr. Bergel of Messrs. Roche Products, Ltd., for specimens of reductone, reductic acid and hydroxytetronic acid which we have compared with the apparent vitamin C in walnuts, and to Miss Elaine Finnigan and Miss Valerie Pritchard for assistance in making the extracts.

Full details of this work will be published elsewhere.

## Thymol Turbidity Test: a New Indicator of Liver Dysfunction

IN the course of work on the serum colloidal gold reaction[1,2] it was noted that the thymol which was at first used to inhibit the growth of moulds in the barbitone buffer ($p$H 7·8) produced a marked turbidity or precipitate with certain sera. These sera were usually from patients with parenchymatous liver disease and also gave positive colloidal gold reactions, and it soon became evident that there was a close correlation between the thymol turbidity and the gold test. Phenol and many of its substitution products gave similar results in suitable concentrations, and there was a direct relationship between the molecular weight, the solubility and the precipitating power. Thus six typical compounds required the following concentrations to produce equal degrees of turbidity at $p$H 7·8, $\mu = 0{\cdot}01$, when added to serum from a case of infective hepatitis. In each case the same solutions produced negligible effects with normal serum.

| Compound | Equivalent concentration | Molecular weight | Solubility (approx.) |
|---|---|---|---|
| Phenol .. .. | 1·5 per cent | 94 | 5·1 per cent |
| Cresols (*o*, *m* and *p*) | 0·75 ,, | 108 | 1·8–2·5 ,, |
| Xylenol (1, 2, 4) .. | 0·4 ,, | 122 | 0·79 ,, |
| Naphthol ($\alpha$) .. | 0·10 ,, | 144 | 0·11 ,, |
| Thymol .. .. | 0·11 ,, | 150 | 0·11 ,, |
| Carvacrol .. .. | 0·11 ,, | 150 | 0·12 ,, |

It is evident that in this series, with increasing molecular weight, the solubility falls off more rapidly than the concentration required for effective precipitation, so that higher homologues such as cholesterol are too insoluble to give a positive result. These considerations suggest analogies with the Pandy test for globulin in cerebrospinal fluid which uses saturated phenol solution, and with the cephalin-cholesterol flocculation test of liver function[3]. It

seems extremely probable that both these tests depend upon the same principle, the function of the cephalin being to keep the cholesterol in solution. On this basis thymol occupies a convenient intermediate position for use with serum, as it is just soluble enough to produce a satisfactory result in saturated solution. Being effective in low concentration, it has the additional merit of simplifying the analysis of the precipitate. No other compound tested was superior to thymol.

As with the gold reaction, changes in the $p$H and in the ionic strength of the medium exerted a marked influence on the result, so that at $p$H 5 turbidity was increased but the test lost all specificity. After numerous trials the following technique was finally adopted and has now been used in some 450 cases.

*Thymol buffer*, *pH* 7·8, $\mu = 0{\cdot}01$. Add 500 ml. of water to 1·03 gm. of sodium barbitone, 1·38 gm. of barbitone, and approximately 3 gm. of thymol. Heat just to boiling point, shake well and cool thoroughly. The mixture should now be turbid. Seed with a small amount of powdered thymol crystals, shake and allow to stand overnight at a temperature of 20–25° C. Finally shake again and filter the clear solution from the crystalline deposit.

*Method*. Add 60 volumes of buffer to 1 volume of serum, allow to stand for half to one hour and compare in a comparator with the turbidity standards of Kingsbury *et al.*[4]. 3 ml. of buffer and 0·05 ml. of serum are convenient volumes to use. The standards are those in common use for urine protein estimation and can be obtained commercially[5]. If the turbidity exceeds the 100 mgm. per cent standard, dilute with a further measured volume of buffer as required. When the test is positive, flocculation frequently occurs on standing overnight, but this is not an essential part of the test. The result is recorded in arbitrary units equal to the appropriate standard divided by ten with allowance for dilution. Thus if the final dilution is 1 in 120 and the mixture then matches the 70 mgm. per cent tube, the result is 14 units. Normal sera give values from 0 to 4 units.

The precipitate in typically positive cases contained 6·0 per cent N, 0·33 per cent P, 32 per cent thymol, and 11·8 per cent cholesterol (average figures). It could be redissolved in weak alkali and was then completely precipitated with one-third saturated ammonium sulphate. It therefore appears to be a globulin-thymol-lipoid complex with the following average composition: protein 37·5 per cent, thymol 32 per cent, cholesterol (half esterified) 16·5 per cent, and phospho-lipid calculated as lecithin 8·0 per cent. The protein is probably mainly the gamma globulin which is known to be concerned with the cephalin-cholesterol test and with the gold reaction[6]. The chemistry of the test is not understood; but it appears that the phenolic grouping has a special affinity for gamma globulin under the conditions employed, although other proteins are precipitated at more acid reactions or with higher concentrations of precipitant. The total serum globulin is above normal in about half the cases with positive thymol tests.

A fuller account will appear elsewhere. In general, the results have been similar to those obtained with the serum colloidal gold reaction[1,2], being positive in 120 out of 130 cases of infective hepatitis (mean 10·3 units, standard error 0·44), in 13 out of 13 cases of cirrhosis ($14{\cdot}2 \pm 2{\cdot}0$), and only weakly positive in 3 out of 38 cases of obstructive jaundice ($1{\cdot}2 \pm 0{\cdot}27$). The thymol test was more often positive than the gold test in Weil's disease and was less often positive in chronic infections. It is therefore rather more specifically related to liver disease than is the gold test, and should be of value in the differential diagnosis of jaundice and as a general indicator of liver dysfunction.

## Barotaxis in Diptera, and its Possible Significance to Economic Entomology

VARIOUS authors have noted an apparent correlation between the degree of activity of insects and the barometric pressure. I have recently completed an investigation of the conditions governing the aerial distribution of insects. The completed work is to be published elsewhere, but it has been thought advisable to direct attention to a phenomenon which came to light during laboratory experiments on the effects of decreased pressure upon insects.

It was noted that certain insects, particularly Diptera, consistently reacted to slight decreases in pressure with a marked increase in flight activity. This increase in activity occurred within the pressure range corresponding to the height interval between sea-level and about 1·5 km. The activity again became normal at still lower pressures.

It must be stressed that this increasing activity is not a distress reaction. The increase occurs regardless of the rate of decrease in pressure, within a zone of reasonable temperature. It occurs when ample time is allowed for acclimatization at given pressure levels.

Not all orders of insects exhibit such a response. In the case of the Diptera, the response is so marked that it should be considered of barotaxic origin. At the present time, the underlying physiology is not clear. However, Glick[1], in commenting on the results of his aircraft collections, notes that Diptera were taken in the first 1·5 km. of the atmosphere in consistently greater numbers than were any other orders. Since the collections were made under a variety of weather conditions, it does not seem reasonable to account for the above simply by assuming numerical superiority. Moreover, species of Coleoptera and Hymenoptera were the next most abundant within this height-interval. It may be significant that these three orders possess highly developed nervous systems. It is probable that their consistent occurrence at higher elevations arises from a favourable response to lowered pressure rather than from sheer weight of numbers.

Although the above observations are chiefly related to the distribution of insects in the upper air, they may be of value when applied to the bionomics of dipterous species at the surface. Underhill[2] noted that certain Simuliids fed more actively at low pressures, or during periods of rapidly falling pressures. It is likely that this is another manifestation of the general increase in activity.

I would suggest that, in future, more attention be given to the correlation of surface pressures with field observations of dipterous species, particularly in those problems related to variations in the activity of Diptera attacking man and animals. By a consideration of the surface pressure distribution, it may be possible to forecast changes in the activities of adults in the field, provided the temperature and other factors are favourable to activity. In this regard, the effect of the winds around areas of low pressure should be considered.

## Phase Difference Microscopy

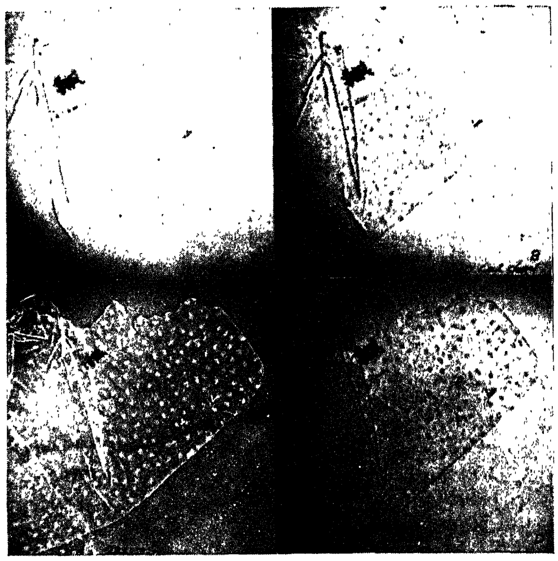
THE microscope does not reveal detail in uncoloured, transparent specimens even though it is known to be present and of sufficient size to be resolvable. When the detail includes regions of different refractive index, phase differences will be involved in light passing through the specimen, and if these phase differences are changed into intensity differences, the detail may be seen since the eye is sensitive to the latter although not to the former.

This change can be accomplished by inserting an annular stop into the condenser of the microscope and inserting a phase plate into the objective at its back focal plane. The phase plate consists of an annulus having a different transparency from the rest of the plate and of proper size to intercept the light coming directly from the opening in the condenser. The plates can be made so that the detail in the specimen may be seen either brighter or darker than its surroundings.

Abbe considered phase differences, but made little practical use of them. Conrady and Rheinberg[1] used phase difference microscopy to show and photograph a grating. Zernike[2] extended the treatment of these differences and urged their use in microscopy. Köhler and Loos[3] used his method with an annular plate and described some of the advantages of this kind of microscopy. The general theory and optical design have been extended in our Research Division by Dr. Harold Osterberg and Dr. R. K. Luneberg, coating methods for the phase plates have been developed by Dr. Helen Jupnik and practical tests and applications have been made by me, all working under Mr. A. H. Bennett, director of research.

The Spencer equipment includes a variety of phase plates having *both* retarding and absorbing properties of improved thin-film coatings. Both positive and negative plates are available for a range of 0–0·4 $\lambda$ retardation and 0–100 per cent transmission. *Absorption differences* have been found by us to be as important as retardation differences in making some specimens visible under the microscope. The microscope exhibited at the Cleveland meetings of the American Association for the Advancement of Science had the phase plates mounted in a disk so that they could be rotated successively into place within the objective.

Phase difference microscopy has been found useful with unstained, transparent tissues, both plant and animal. Fig. 1 shows the appearance of epithelial tissue, living and unstained, from the nictitating



FROG NICTITATING MEMBRANE EPITHELIUM. × 40 APPROX. *A*, ORDINARY MICROSCOPE, APERTURE FILLED. *B*, SAME, APERTURE HALF FILLED, DETAIL LARGELY DIFFRACTION PATTERNS. *C*, BRIGHT-, AND *D*, DARK-PHASE WITH PHASE-DIFFERENCE MICROSCOPE.

membrane of the frog eye. The fine detail in fibroblasts from a chick embryo should be seen, but is not seen with the usual microscope objective. (Stopping the condenser down to give a narrow illuminating cone loses the fine detail in a lot of diffraction patterns.) Bacteria, blood cells, mould and Protozoa can be made clearly visible against their background; this facilitates study and counting. The resolution of the lenses appears not to be reduced, and considerable time and material are saved by not staining the specimens. The 'visualization' of transparent cells will give an interesting check on previous information obtained from killed and stained cells and tissues.

Industrial applications may include the examination of transparent fibres, as glass and plastics, and surface detail on materials embedded in media of slightly different index. Small particles, within the limit of resolution of light microscopy, may be counted and measured, as in homogenized milk and in mayonnaise. The microscopic polishing marks on a transparent glass surface have been demonstrated and photographed in our laboratory.

The positive phase difference giving dark detail is more useful for measurement, and the negative phase showing bright particles is preferable for counting. Either appearance is possible with no damage to the specimen. When the particles are of differing size, as within a large *Paramecium*, they may selectively be made lighter or darker with respect to those of different size. Magnifications used range from 100 to 2,000 diameters and include dry and homogeneous immersion objectives. This development extends greatly the usefulness of the light microscope to include transparent materials of importance to several branches of science, medicine and industry.

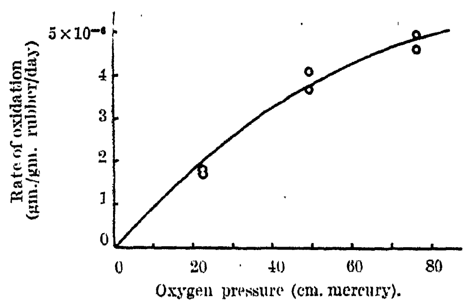
## Reaction between Oxygen and Rubber

SEVERAL investigations[1,2,3,4] on the effect of pressure on the reaction between natural rubber and gaseous oxygen in its initial stages have been made by following the rate of disappearance of the oxygen in a closed system. In the experiments, the oxygen pressure decreased spontaneously as oxygen combined. Under these conditions, the results may be vitiated if time-effects occur such as might arise from the rate of combination of oxygen dissolved in the rubber outpacing the rate of dissolution of fresh gas, or from the formation of unstable oxidation catalysts.

We have carried out oxygen absorption experiments under conditions of constant pressure, with rubber specimens for which we have evidence that their state of subdivision is such as to prevent any complication from diffusion effects, and have come to the following conclusions.

1. At constant pressure the rate of oxidation reaches a constant and reproducible value. (Our experiments have been confined to combined oxygen proportions not exceeding 1 per cent by weight.)

2. Contrary to earlier suggestions[4], the oxidation-rate is greater the greater the oxygen pressure (Fig. 1).



OXIDATION OF UNVULCANIZED SMOKED SHEET RUBBER AT 40° C.

3. The rate of oxidation using dry air free from carbon dioxide is greater than that using undiluted oxygen at the same partial pressure.

The following further conclusions are based on experiments involving alteration in oxygen pressure.

4. After storage in a vacuum, the rate of oxidation of rubber in oxygen under constant pressure slowly increases, for several hours, from zero to the 'equilibrium rate' for that oxygen pressure. This period is considerably greater than that required for solubility equilibrium.

5. If, after the rate of oxidation under constant pressure has become constant, the oxygen pressure is reduced to a new constant value, the rate of oxidation falls slowly for several hours from a high initial value to the new constant rate corresponding with the lower pressure. This high initial rate is sometimes greater than the constant rate at the higher pressure. These statements may also be true in strict converse for an increase in oxygen pressure.

6. The persistence of an oxidation-rate greater than the 'equilibrium rate' immediately succeeding a reduction in pressure (see 5) can invalidate conclusions from experiments involving a changing pressure, and may explain the lack of agreement between results of earlier workers.

A detailed account of this work will be published later.

## Ethereal Sulphate Content of Agar Specimens

IN 1942, through the kindness of Dr. A. P. Orr of the Marine Station, Millport, specimens of agars of known history were examined to see if evidence could be secured for the formulation of Jones and Peat[1], which demands a relatively high sulphur content (S, 1·8 per cent; that is, $SO_4$, 5·4 per cent).

The specimens had been extracted from the algæ with boiling water without any chemical treatment, and the agars purified by freezing and thawing; the results are tabulated below:

| Plant | Source | Ash | $SO_4$ (in ash) | $SO_4$ (total) |
|---|---|---|---|---|
| *Gracilaria confervoides* | Plymouth | 2·2% | 0·9% | 1·3% |
| *Gelidium crinale* | Dunure (Ayrshire) | 3·6 | 0·7 | 1·4 |

These figures may be compared with those reported by Barry and Dillon[2] for an agar extracted from *Gelidium latifolium*, which gave ash, 2·6 per cent; S, 0·36 per cent. It is clear that none of the above specimens contain sufficient sulphate to account for the proportion of 2 : 4-dimethyl-3 : 6-anhydro-β-methyl-*l*-galactoside (9 per cent[1]; 11·5 per cent[3]) isolated from methylated agar, on the former of which the 'sulphate formula' proposed by Jones and Peat is based.

From their experiments with periodic acid, Barry and Dillon[2] concluded "that the 3 : 6-anhydro-*l*-galactose isolated from agar in the form of its 2 : 4-dimethyl derivative is not an artefact produced during the methylation process[1], but a constituent of the agar molecule". That this appears to be true for commercial samples of agar has been pointed out previously[3,4,5,6], but it is difficult to believe that there is no connexion between the 3 : 6-anhydro-*l*-galactose units and the sulphate groups, since the alkaline hydrolysis of methylhexoside sulphates gives rings of this type[6]. If, as Jones and Peat[1] suggest, all the galactose residues which ultimately become 3 : 6-anhydro-*l*-galactose residues carry sulphuric ester groups at the same time, the present evidence points to the conclusion that most of these sulphate residues are removed at some stage prior to the actual extraction of the polysaccharide from the plant. An alternative view would be a gradual removal of sulphate groups during the life of the plant with 3 : 6-anhydride formation, followed by the formation of ethereal sulphates on other galactose residues, the sulphur content remaining approximately constant throughout.

Finally, it should be stated that there is as yet no direct evidence that the sulphate groups remaining in the agar after isolation are located on $C_6$ of the

$l$-galactose residues, although at the time of the publication by Jones and Peat[1] this was perhaps a natural assumption. The ethereal sulphate could indeed be situated on $C_3$, since recent experiments in this laboratory have shown that methylglucofuranoside-3-sulphates yield 3 : 6-anhydrides on alkaline hydrolysis. It may be added further that if the hydroxyl groups on $C_3$ were thus esterified, the agar would possess no $\alpha$-glycol groupings, and would therefore not react with periodic acid, thus providing an alternative explanation for the results of Barry and Dillon[2]. It should be noted, however, that this suggestion that the sulphate residue might be found on $C_3$ is not put forward as a rival hypothesis to that of Jones and Peat[1], but as a possible alternative, to emphasize the fact that additional work on agar specimens of known history is needed before further progress can be made in determining the structure of this polysaccharide.

## Non-conservative Fundamental Particles

IN view of certain possibilities, for example the still open possibility of the non-existence of the neutrino, it may be interesting to set up an equation for a fundamental particle which, in the restricted relativity approximation, does not obey the energy conservation law.

Such a non-conservation property is easily arrived at by taking a Lagrangian which depends explicitly on the four co-ordinates. It is remarkable, however, that such a Lagrangian, or alternatively the corresponding equations, are almost automatically obtained, in an elegant way, by starting from the Dirac form and merely taking full account of the Lorentz invariance. The simplest form of equation is obtained as follows. Let us start from the Dirac equation

$$\gamma^{\mu}\,\partial_{\mu}\,\psi + k\,\psi = 0 \quad (\partial_{\mu} = \partial/\partial x^{\mu}).$$

It is well known that the Lorentz invariance is not altered if one adds a term of the form $A_{\mu\nu}\,\gamma^{\mu}\,\gamma^{\nu}$, $A_{\mu\nu}$ being an antisymmetric tensor of second rank. The simplest tensor of this type attached to the particle is obviously $x_{\mu}\,\partial_{\nu} - x_{\nu}\partial_{\mu}$. In order to make it invariant also under a change of origin, we take $(x_{\mu} - b_{\mu})\,\partial_{\nu} - (x_{\nu} - b_{\nu})\,\partial_{\mu}$, $b_{\mu}$ representing the co-ordinates of a point in space-time, the simplest case again being $b_{\mu} =$ constant. Putting therefore $m^{\mu\nu} = i/2.(\gamma^{\mu}\gamma^{\nu} - \gamma^{\nu}\gamma^{\mu})$, the new equation is, in the case of no field :

$$(1) \quad \gamma^{\mu}\,\partial_{\mu}\,\psi + i\lambda\,(x_{\sigma} - b_{\sigma})\,m^{\sigma\mu}\,\partial_{\mu}\,\psi + k\psi = 0 \qquad (\lambda = \text{real constant}).$$

It is obvious that dual terms in $\gamma^{\rho}\gamma^{\sigma}\gamma^{\tau}$ and $\gamma^{1}\gamma^{2}\gamma^{3}\gamma^{4}$ could also be added without disturbing the invariance ; but as only the contribution of the $\gamma^{\mu}\gamma^{\nu}$ term brings something new, we shall leave them out at the present stage.

The particle defined by (1) has some remarkable properties close to those of Dirac's electron. It has a constant charge, and we may therefore call it a 'particle'. Its main feature is the spontaneous change of energy and momentum. The total amount of energy varies, even in the case of no field and even if the particle is 'at rest' and therefore has a vanishing kinetic energy. As the time passes, the particle loses or gains energy, even when resting, just like, for example, a living organism does. This change is connected with the existence of the new term in the equation and is proportional to the 'age' of the particle and to the constant $\lambda$. It can be computed from the expression of the symmetrical energy-momentum tensor[1] $T^{\mu\nu}$, which leads to :

$$\partial_{\nu}\,T^{\mu\nu} = 2\lambda\,(x^{\mu} - b^{\mu})\,(\partial_{\rho}\psi^{*}\,i\gamma^{4}\,m^{\sigma\rho}\;\partial_{\sigma}\psi),$$

giving thus a physical interpretation of the constant $\lambda$.

To define such a particle one must give, apart from its mass, a constant $\lambda$ *and* a point in space-time $b_{\mu}$, intrinsically defined as the (chosen) point around which the particle is almost conservative, behaving, in fact, like a classical Dirac electron. To achieve the definition of a particle by giving not only a mass and $\lambda$, but also a point in space-time, is most unfamiliar but by no means physically absurd. One can picture, for example, a conservative particle bound to some system and escaping from it at a given moment. If, when escaping from the nucleus (or in general when being created), the particle acquires the non-conservation character, the moment and place where this happens are indeed an essential feature of its definition.

The symmetry of $T^{\mu\nu}$ causes the total angular momentum at the fixed point $b_{\mu}$ to be constant.

$\lambda$ is not necessarily small, so that the supplementary term cannot be always considered as a small perturbation. In this case one gets interesting results by investigating what happens around a certain point $x^{k} = a^{k}$ at a definite instant $x^{4} = a^{4}$, that is by assuming that $a^{\mu} =$ const. The equation is then solved by a plane wave $\psi = A \exp i(p_{\mu}x^{\mu})$, where $p_{\mu}$ is proportional to the energy and momentum.

The classical relation $(W/c)^{2} = \vec{p}^{\,2} + w^{2}c^{2}$ between energy and momentum is no longer valid ; the new relation shows that, in the Newtonian approximation, the total energy is composed of the kinetic energy arising from the translation movement of the particle, plus a rotation energy, a fact which can be foreseen from the original form of the equation.

Unlike Dirac's case, the quantum mechanical treatment of this particle is essentially one which uses an indefinite metric in Hilbert space[2], as the normalization integral is

$$\int \psi^{*}\,[1 + \lambda\,(x_{k} - b_{k})\,\gamma^{k}]\,\psi\,d\tau.$$

The Hamiltonian form $\partial\psi/\partial t + iH\psi = 0$ is easily obtained and brings to light the discontinuity sphere $1 - \lambda^{2}\Sigma(x_{\varkappa} - b_{\varkappa})^{2} = 0$, which plays an important part in the discussion and gives a geometrical interpretation of the newly introduced constant $\lambda$.

The striking fact about the above equation is that it follows quite naturally from a straightforward application of restricted relativity to the problem of the electron. This does not mean that it necessarily fits the physical reality, but seems to point towards the fact that its study might be worth while.

I am indebted to Prof. P. A. M. Dirac for invaluable discussion.

## 'Coloured Anthers': a New Monofactorial Character in Wheat, *T. vulgare*, Host.

IN most bread wheats the anthers are yellow but in occasional lines they are a characteristic purplish-pink colour. During some experiments with hexaploid or *vulgare*-series wheats a cross was made between a yellow-anthered spelt wheat, *Triticum spelta*, L., and a coloured-anthered bread wheat, *T. vulgare*, Host. (*T. spelta* is simply a variety of *T. vulgare* with the '*spelta*' gene or gene block $K^s$ on one of the pairs of chromosomes of the A or B sets instead of the allelomorph $k$ for the round type of glume of *T. vulgare*). Of the $F_2$ plants examined at anthesis, 28 had coloured anthers (*CaCa* or *Caca*) and 13 had yellow (*caca*).

| Anthers | Observed (O) | Calculated (C) | O–C | (O–C)² | (O–C)²/C |
|---|---|---|---|---|---|
| Coloured | 28 | 30·75 | —2·75 | 7·56 | 0·246 |
| Yellow | 13 | 10·25 | 2·75 | 7·56 | 0·735 |
| Total | 41 | 41·00 | 0·00 | $\chi^2$ = 0·981 | |

With $\chi^2 = 0{\cdot}981$, for 1 degree of freedom, $P = 0{\cdot}5$–$0{\cdot}3$, showing a good agreement with a 3 : 1 ratio.

After harvest, of the 41 plants classified, for various reasons only 34 remained which could be classified with respect to the spelta/round glume characters. Classification was not easy as the parental bread wheat line is one which itself has a slightly keeled glume. However, the following results were obtained:

| Class | Observed (O) | Calculated (C) | O–C | (O–C)² | (O–C)²/C |
|---|---|---|---|---|---|
| Coloured keeled | 17 | 19·125 | —2·125 | 4·52 | 0·236 |
| Coloured round | 6 | 6·375 | —0·375 | 0·141 | 0·022 |
| Yellow keeled | 10 | 6·375 | 3·625 | 13·14 | 2·062 |
| Yellow round | 1 | 2·125 | —1·125 | 1·27 | 0·596 |
| Total | 34 | 34·00 | 0·000 | $\chi^2$ = 2·916 | |

With $\chi^2 = 2{\cdot}916$, for three degrees of freedom, $P = 0{\cdot}5$–$0{\cdot}3$, showing a good agreement with the assumption that the coloured/yellow anther alleles (*Ca/ca*) are monofactorial and independent of the keeled/round glume factors ($K^s/k$), giving a 9 : 3 : 3 : 1 ratio in the $F_2$.

The number of simply inherited characters in wheat is remarkably small, so that the present one, which does not appear to have been described before, may prove useful as a marker gene. That other types of coloured anthers may give 15 : 1 or 63 : 1 ratios is quite possible since multiple factors are common in wheat: the character described might well be only one of two or three such allelomorphs.

Classification is good but inconvenient unless the plants can be grown where they may be examined every day. At anthesis there is little difficulty in classifying a plant, though sometimes (in heterozygotes ?) the colour is pale or restricted to the base of the anthers. After shedding pollen, the anther seems to continue drying and become a dirty white colour indistinguishable from that of an old dehisced yellow anther. Thus classification must be done during anthesis. The temperature during development seems to be rather important—all the $F_1$ plants were grown in a greenhouse, and they, as well as plants from similar crosses and plants from the line of the coloured parent, all had yellow anthers. The $F_2$ was grown outside, and the cool summer of 1944 was favourable for the expression of the character in these plants and in the parental and similar lines.

Thus the character 'coloured anthers' offers a new allele which, at least in this case, is easily classifiable, is monofactorial and is independent of the keeled/round glume allelomorphs.

## Shape of Sea-Urchins

IN the latest edition of "Growth and Form" (1942), Sir D'Arcy Thompson has directed attention to the analogy between the shapes of drops of such a liquid as *ortho*-toluidine when resting on the bottom of a vessel filled with water, and the shapes of sea-urchins. Thus a small drop remains practically spherical while a large drop spreads itself out, or more or less sags under its own weight (pp. 946–48).

In this way, Sir D'Arcy Thompson seeks to account for the pronounced flattening of some of the sea-urchins while he attributes the marked conical shape of others to the presence of masses of *fatty, oily eggs*, which have a density less than that of sea-water and thus raise the upper surface.

Some recent work carried out at Plymouth, however, would indicate that both these concepts require revision.

It is not denied that a sea-urchin with a very flexible shell might become flattened under its own weight, but flattening does not necessarily imply a non-resisting shell.

One of the sea-urchins recently studied was *Psammechinus miliaris* (Gmelin), which was found to have a density of 1·3457 at 14° C. and to contain 55·5 per cent water. The figures represent the mean of four determinations. One of the chief characteristics of this urchin is its marked flattening, its height seldom exceeding half the diameter. The urchin is, however, remarkably resistant to weight. This was proved by the very simple experiment of placing a specimen, after it had drained on filter-paper for a few seconds, under the right-hand pan of a 5 kilo Oertling balance. Weights equal to 4 kilos were placed on the left pan and two weights each of 2 kilos were placed on the right pan.

On removing the weights carefully from the left pan the right pan rested on the urchin, and it was found that the animal could support the whole 4 kilos without undergoing injury, and since the urchin in question only weighed 19 gm. it was thus supporting more than two hundred times its own weight.

The second concept, namely, that of the upper part of the shell being raised by the presence of ova lighter than sea-water, also requires moderation, for the ova of sea-urchins contain very little fat and at no period of their existence is their density less than that of sea-water. The whole concept of buoyancy by oil drops in sea-water requires revision, for though such oil drops are fairly common their density is usually about 0·9. Thus in marine invertebrates, if the density of calcite is 2·7 and that of silica 2·5, that of chitin 1·4 and of protoplasm itself 1·05, the presence of a small amount of oil or fat with a density of 0·9–0·8 can have very little buoyancy effect. It is very doubtful whether any appreciable buoyancy effect due to fats or oils is to be found except among

the mammals. The ova of *Acanthias vulgaris* contain practically 30 per cent fat, but the ova still retain a density of 1·055.

It is true that the flattening might take place during the very early stages of development of the sea-urchins, but at this stage there would scarcely be any pronounced ovaries; and again if these supposedly light ova could lift the upper shell of the urchin, would it not occur in one sex only and thus impress marked sexual dimorphism, which appears to be so markedly lacking among the echinoids?

## A New Type of the *Salmonella* Genus

In a previous communication[1], as a matter of preliminary report, a few properties of *S. hormæchei* were described, the antigenic structure of which differed from those of all known types.

This *Salmonella* was isolated by means of Kauffmann's 'combined method' from the ovary of a hen the blood of which gave a positive reaction with the pullorum antigen coloured and dead.

*S. hormæchei* presents morphological, tinctorial and culture characters, which coincide, except for the slight variations described below, with the bacteria belonging to the *Salmonella* genus. It is mobile. It develops vigorously in the usual culture media. In agar, the culture is adherent. In liquid media, a noticeable turbidity can be observed, which later becomes intense, the sediment is abundant and does not easily disintegrate by agitation. It shows in the liquid mass, as well as in contact with the inner wall of the container, a fine granulation. The formation of a slight superficial veil can be noticed.

It ferments, with the production of acid and gases, dextrose, arabinose, dulcitol, galactose, rhamnose, lævulose, maltose, manitol, manose, sorbitol, trehalose and xylose. It does not attack starch, erithrite, inosite, inulin, lactose, raffinose, saccharose or salicine. It does not produce indol. It does not coagulate milk. It does not produce hydrogen sulphide. It does not liquefy gelatine. It gives a positive reaction with Stern's test; Bitter, Weigmann and Habs media, positive, with dextrose and arabinose; subpositive, with dulcitol and rhamnose; Simmons media, with arabinose, dextrose, dulcitol, rhamnose and citrate, all positive. Positive reaction opposite to *d*-tartrate, mucate, *l*-tartrate, *i*-tartrate and citrate. Reduces nitrates to nitrites; does not hydrolyse urea.

The antigenic structure, which has been studied by means of the 'mirror test', indicates that *S. hormæchei* possess the same antigenic '*O*' thermostable of *S. ballerup*; but on the other hand it has not been possible, at least thus far, to find antigen *Vi*.

The flagellar antigens present special interest, since they are considered to be an antigenic 'mosaic', constituted by two fractions not referred to hitherto, where one of them corresponds to '*H*' antigen specific, which we designate by the symbol $Z^{30}$, and the other is common with *S. ballerup*; we distinguish it by the symbol $Z^{31}$. Concerning the latter, researches are being continued. The abbreviated serological formula of *S. hormæchei* is represented in the following form, XXIX.$Z^{30}$.($Z^{31}$).—., where $Z^{31}$ is in brackets in order to show that in certain circumstances it may be lacking. Inoculations in mice, guinea pig and rabbits, by the oral, subcutaneous and intraperitoneal routes, have not caused death in any case.

*S. hormæchei* corresponds to the second new type of *Salmonella*, isolated and classified in Argentina by me, the first having been *S. bonariensis*.

## Collapse of Determinism

Now that this subject has been raised again in these columns[1] I should like to ask a question which puzzles the 'everyday' physicist who is paid to keep his feet on the ground.

In his Guthrie Lecture, Prof. Whittaker, after discussing hidden parameters in relation to the reflexion or transmission of light, says: "Thus the choice between the alternatives of transmission and reflexion at the Nicol is truly indeterminate, so far as individual photons are concerned, and is qualified only by a statistical regularity when great numbers of events are considered" (that is, $\cos^2 \varphi$ of the intensity is transmitted and $\sin^2 \varphi$ reflected).

My difficulty is that if the final result of, say, one million, or billion, photons is regular (that is, determined), then how can the choice of any (except the first few) be individually indeterminate? Surely there must be some influence set up by the first 999,000 photons which will bias the indeterminate motion of the last 1,000 in order to balance the statistical result if the first arrivals have been a little too free with their indeterminacy. The introduction of a certain experimental error in measurement of the intensity does not affect the argument.

The difficulty is so obvious that I feel one has the right to demand a *simple* explanation to clear it up. It is independent of any particular knowledge of photons or of the mathematics of indeterminacy.

WILFRED W. BARKAS.

"Under Cross",
Whiteleaf,
Via Aylesbury, Bucks. Oct. 11.

[1] *Nature*, **154**, 464 (1944).

FOR a profound study of the question of determinism in physics, reference may be made to Prof. J. von Neumann's "Mathematische Grundlagen der Quantenmechanik", p. 157 *et seq.* I doubt if any very simple treatment can be quite rigorous; but in connexion with Mr. Barkas's point, the following line of thought might be profitable. If a coin is tossed a thousand times and the number of occurrences of heads recorded, and if this experiment is repeated a very great number of times, there will be a statistical regularity in the records, which may be calculated by the ordinary theory of probability. Does the calculation at any stage involve the assumption that the tossing of coins is crypto-deterministic, or does it involve only the assumption (as regards the tossing) that there is symmetry in the system, so that there is no reason to expect heads rather than tails in a single trial?

E. T. WHITTAKER.

# PENICILLIN TREATMENT

A SPECIAL issue of the *British Journal of Surgery* (**32**, 105–224, 1944. 12*s*. 6*d*. net) is devoted to reports by British and United States medical men on the treatment with penicillin of battle casualties which has been carried out during the present War. Everybody who is at all interested in penicillin should read this valuable and beautifully produced record. It is only two years, Major-General L. T. Poole explains in his foreword, since Sir Howard Florey offered to the British War Office a small quantity of penicillin for trial in the Middle East. This was successfully flown out there, in spite of the difficulties of communications at that time. The strength of the first batches received by the Army varied from 30 to 40 Oxford units per mgm. Nowadays some of the preparations used have a strength of about 1,600 units per mgm. This is one measure of the progress made in this short period. The progress in production may be gauged by the fact that the Penicillin Team sent to North Africa in May 1943 was equipped with ten million units, whereas later it was possible to send by air regularly to Italy twenty million units a day.

Penicillin treatment is not, of course, to be lightly undertaken. Everywhere in this record of its use the necessity for the training of teams of workers for its application is emphasized. Sir Howard Florey and M. A. Jennings deal with the general principles of the treatment. They summarize the properties of penicillin, which Sir Howard Florey has already described in *Nature* (Jan. 8, p. 40, 1944). Modern methods of its administration are less well known and are here described by Sir Howard and M. A. Jennings and by other contributors. The rapid absorption and elimination of penicillin must always be borne in mind. Relatively large doses must be given and these must be frequently repeated. A continuous concentration of the drug must be maintained in contact with all the infected tissues. For systemic administration penicillin is usually given by intramuscular or subcutaneous injection. After intramuscular injection the maximum concentration in the blood is reached after fifteen minutes, so that little is gained by intravenous administration. Absorption from subcutaneous injection is somewhat slower. Excretion in the urine begins as soon as the penicillin reaches the blood. As a rule, in the fourth hour after a dose of 15,000 units, a bacteriostatic concentration no longer exists in the blood, so that the dose should be repeated every three hours. Excretion is so rapid that there is probably no advantage in increasing the dose of 15,000 units originally established by the Floreys as the generally effective dose. The same total dose can be given by a continuous intravenous or intramuscular drip or by continuous subcutaneous infusion. For local administration, penicillin in the form of a powder, a solution or in creams can be used. Brigadier R. W. Mackenna (*The Lancet*, 314, Sept. 2, 1944) has devised a dosimetric spray for the treatment of skin diseases.

Because penicillin must be brought into contact with every part of the infected tissues, all dead tissue must be removed. Penicillin is not, therefore, a substitute for surgery, and most of the surgeons contributing to this symposium emphasize this fact. For the same reason too much should not be expected from it when certain kinds of severe injury are being treated. Major R. Furlong and Major J. M. P. Clark, for example, reporting on the treatment of open fractures of the femur, conclude that the penicillin treatment given by them did not control sepsis fully; but this kind of battle casualty presents the surgeon with great difficulties. It may, for example, be difficult to obtain adequate drainage of all parts of such extensive and complex injuries as these, and, as the authors remark, "penicillin cannot be expected to clean Augean stables". Lieut.-Colonel Jeffrey, who succeeded Lieut.-Colonel Ian Fraser as penicillin surgical officer in North Africa and Italy when the latter was invalided home, reports, however, in his article on battle fractures in Italy, that penicillin, in his experience, very largely controlled the infection. Without the assurance that this would be so, the necessary radical surgical treatment would not have been justified in such cases as compound fractures more than twelve hours old. The authors of both these articles on battle fractures record a reduction of mortality and fewer losses of limbs as the result of the use of penicillin.

The hastening of healing by early closure of the wound and the instillation of penicillin through fine rubber tubes placed in the wound is discussed by Lieut.-Colonels F. H. Bentley and J. J. Mason Brown. Photographs illustrate the method of doing this. Penicillin may also be injected with a needle. Like some other substances, penicillin passes only slowly from the blood into the cerebro-spinal spaces, and into the pleural and probably the joint cavities also. For meningitis, Sir Howard Florey and M. A. Jennings state that intrathecal injection by the lumbar route or into the lateral ventricles of the brain is most effective. Fleming and others have shown that this method maintains a bacteriostatic concentration in the cerebro-spinal fluid. The article by Brigadier Hugh Cairns deals with this method for the treatment of wounds of the head and spine, to which penicillin can be applied either as a powder, as a solution instilled through rubber tubes in the wound, by systemic routes or by injection of it by the lumbar route or into the lateral ventricles of the brain. Sulphadiazine or sulphamezathine are, he says, useful additional means for the prevention or prophylaxis of meningitis. One is reminded here of the claims made by some Russian workers that tetanus can be successfully treated by a similar injection of tetanus antitoxin into the lateral ventricles of the brain and the cerebrospinal spaces, the so-called blood-brain barrier being thus overcome. Brigadier Cairns, like his colleagues, emphasizes the need for "careful surgical toilet" in addition to the penicillin. Two articles describe the use of penicillin for treatment of wounds of the chest, and the value of penicillin is agreed, although its value for cases of hæmothorax is less certain.

The two articles on the treatment of gas gangrene indicate that more work is required on the treatment of this condition with penicillin. In one of these articles, which is illustrated by photographs in colour of the progress of battle wounds, Col. Elliott C. Cutler and Major W. R. Sandusky, United States Army, record that penicillin did not prevent the development of gas gangrene in seven cases treated locally and parenterally. This number of cases is, they conclude, too small to enable them to assess the real influence of penicillin on gas gangrene, but they think that surgical treatment is the main factor in the prophylaxis and treatment. Lieut.-Colonel J. S. Jeffrey and Major Scott Thomson report on thirty-three cases of gas gangrene in Italy and conclude

that penicillin was definitely useful. The causative organism in Italy was *Cl. welchii*.

The use of penicillin for the treatment of venereal disease is described in two articles. Major J. N. Robinson, United States Army, concludes that "penicillin is the most effective agent we have for treating all types of gonorrhœa. If the supply were unlimited, it would be the therapy of choice". Lieut.-Colonel D. M. Pillsbury and Major C. S. Wise, United States Army, report their confirmation of earlier work which showed that penicillin rapidly kills the spirochætes which cause syphilis and causes early regression of syphilitic symptoms; the immediate effects of penicillin are, they think, better than those of the arsenical preparations. The bibliography, which contains, the editors say, references to all the previous published work on penicillin, refers to work on other spirochætal infections, such as relapsing fever.

The low toxicity of penicillin, especially of the purer forms of it now available, is one of its most remarkable features. It is almost certain, say Sir Howard Florey and M. A. Jennings, that such clinical reactions as are seen in some cases are due to the impurities which are present in all preparations of penicillin. There is all the more reason for the warnings which have been issued against the use of 'home-made penicillin' and preparations of other fungi. One of the outstanding features of this symposium is, indeed, the insistence in more than one article of the need for careful technique, which should be carried out by specially trained teams, and for the control of the treatment by the bacteriologist. Penicillin has, moreover, certain definite limitations which are indicated by Sir Howard Florey and M. A. Jennings and by Lieut.-Colonel J. S. Jeffrey. Certain organisms are resistant to it, nor can penicillin act on organisms susceptible to it when these are in dead tissue or in the centre of abscesses or masses of pus; it cannot affect bacterial toxins either. Ignorance or neglect of these facts, inadequate dosage and lack of proper supervision of the technique may result in disappointment. There has, however, been little tendency to neglect adequate surgery or to rely too much upon penicillin. The bacteriological control necessary is well described by Prof. L. P. Garrod and N. G. Heatley in their account of the diagnosis of bacteria in wounds, of the standardization of the Oxford unit (the unit of potency) and the methods of assay of penicillin used for treatment or present in exudates or in the blood or other body fluids.

Major Scott Thomson describes the bacteriological examination of wounds treated with penicillin. "Exacting to handle and unstable though it may be," say Sir Howard Florey and M. A. Jennings, penicillin should not fail if it is given continuous contact with the tissues involved. This is the surgeon's problem and often it is not an easy one. The three main uses of penicillin, Lieut.-Colonel J. S. Jeffrey concludes, are to prevent infection soon after the infliction of the wound (in the forward areas), to control it during the first two weeks (at the forward base hospitals) and to combat infection in the later stages. The routine use of penicillin, he says, saves lives and minimizes functional disability and loss of man-power; it allows more rapid healing than has been possible before. It may therefore be especially useful, as Major-General L. T. Poole points out, to airborne troops, who may have to wait some time before the main forces fighting towards them can evacuate their wounded.

Future work, says Major-General Poole, will seek corroboration of the results already obtained and will tackle the problems which this work has raised. For this the continuation of the existing collaboration of chemists, pathologists, bacteriologists, clinicians and surgeons will be required. The collaboration here recorded between British and United States workers reminds us of the debt we also owe to others in the United States who have helped British workers to produce penicillin in such quantities that we can all now share its benefits. In Great Britain this debt is freely acknowledged. It is but one more instance of that co-operation of the English-speaking peoples which has done so much all over the world for the control of all kinds of human disease.

Since the above was written, a number of articles on penicillin have appeared which are related to several of the points mentioned.

*The Lancet* (348, Sept. 9, 1944), in a valuable annotation on penicillin, discusses the production of penicillin and the regulations which now control the manufacture of penicillin crude filtrate, dried crude filtrate and purified penicillin in the form of its sodium salt, and the good results which have been obtained with crude filtrates. The new regulations do not prevent any hospital from preparing penicillin for its own use. *The Lancet* refers to the full account of the preparation and properties of crude penicillin given by A. M. Fisher (*Bull. Johns Hopkins Hosp.*, **73**, 343; 1943). In the same issue (page 336), I. W. J. McAdam, J. P. Duguid and S. W. Challinor describe the types of apparatus for continuous or three-hourly administration of penicillin. G. V. Osborne (*The Lancet*, 407, Sept. 23, 1944) describes an apparatus for administration by continuous ultra-muscular drip. Dr. C. A. St. Hill (*Brit. Med. J.*, 631, Nov. 11, 1944) describes an apparatus, easily made from routine pathological equipment, for subcutaneous or intramuscular administration of penicillin to infants and young children.

The 'mega unit' of penicillin, which represents a million Oxford units, is discussed in *The Lancet* (522, Oct. 21, 1944); it is used only for ordering supplies in order to obviate the necessity of writing out hundreds of thousands of Oxford units and confusion with the American billion, which is only a thousand million. The international uniform standard and unit of penicillin agreed upon at the recent conference of the Health Section of the League of Nations are described in the *British Medical Journal* (572, Oct. 28, 1944, and *The Lancet*, 574, Oct. 28, 1944).

Lieut.-Colonel J. W. Bigger (*The Lancet*, 497, Oct. 14, 1944; see also p. 508) has described a method of alternately giving and withholding penicillin for infections with *Staphylococcus pyogenes*, based on his view that penicillin acts on bacteria at the time of their division and also actually kills staphylococci. A. M. Fisher (*loc. cit.*; see also *The Lancet*, 348, Sept. 9, 1944) found that it is bactericidal to *S. aureus*. Lieut.-Colonel Bigger believes that the few staphylococci which survive the penicillin do so because they are in a non-dividing phase. He calls them 'persisters', and his method aims at killing them when the penicillin treatment is recommenced.

W. McKissock, V. Logue and I. Bartholomew (*Brit. Med. J.*, 551, Oct. 28, 1944), reporting on the local penicillin treatment of battle wounds of the head, emphasize the need for asepsis.

In view of the desirability of finding some method of slowing down the rapid excretion of penicillin, the work done by K. H. Beyer and his colleagues (*Science*,

100, 107; 1944; see *The Lancet*, 542, Oct. 21, 1944), which indicates that intravenous administration of *p*-amino-hippuric acid delays the renal excretion of penicillin, merits further trial.

Lieut.-Colonel Bigger (*The Lancet*, 400, Sept. 23, 1944) claims that penicillin is, contrary to the statement made about it by many writers, inactivated by human blood or serum. The degree of inactivation varies, however, considerably with different specimens of serum and is much greater at body temperature than at lower temperatures. It may lead the bacteriologist to under-estimate the amount of penicillin in the serum of a patient, particularly when the concentration is low. Inactivation *in vivo* is probably chiefly important in cases in which the excretion by the kidneys is slow. The author, discussing the fact that penicillin is excreted chiefly by the kidneys, refers to Sir. Howard Florey's comparison of the struggle to maintain an adequate concentration of penicillin in the blood to efforts to fill a bath while the plug is out. If, Colonel Bigger says, penicillin is constantly being inactivated by the plasma, we should add to this comparison a running cold tap and, in view of the difficulties of supply, a boilerman highly conscious of the need for fuel economy. The author also discusses the work of C. H. Rammelkamp and S. E. Bradley (*Proc. Soc. Exp. Biol. and Med.*, **53**, 30; 1943), who found that the administration of 'Diodrast' (B.P. diodone) delays the excretion of penicillin.

Marie Kalisova (*Brit. Med. J.*, 597, Nov. 4, 1944) describes "the dramatic effect of penicillin on what would otherwise have been a hopeless case of acute appendicitis" in a child aged four. The penicillin was introduced directly into the peritoneal cavity, and by repeated aspirations of exudate from this cavity and its replacement by penicillin the patient's condition improved and his life was saved.

G. LAPAGE.

## ANTISEPTICS

THE first Lister Memorial Lecture of the Society of Chemical Industry was delivered on November 9 by Sir Alexander Fleming, of St. Mary's Hospital, London, at the University of Edinburgh; the title of Sir Alexander's address was "Antiseptics".

Lord Lister, in his epoch-making work, used carbolic acid as an antiseptic in surgery. This had the advantage of attacking all microbes equally, but the disadvantage of being poisonous to man and of destroying the leucocytes or white corpuscles of the blood which themselves act as the chief weapon in the body's own antiseptic armoury. The latest antiseptics, on the contrary, have a much greater effect against certain bacteria but are less destructive to leucocytes; the antibacterial to antileucocytic ratio of penicillin is 250,000, of sulphanilamide 1,000, but of carbolic acid only ½.

Sir Alexander Fleming described his discovery of penicillin in 1929. There had been nothing in the literature to make anyone suspect that a substance with the chemical constitution of penicillin would have antibacterial value. The discovery had to come by chance, and it was his good fortune that the chance had presented itself to him. While working on quite a different subject he noticed that a mould (later proved to be *Penicillium notatum*), growing as a contamination on a culture plate, made a noteworthy change in colonies of staphylococci on the plate. Thanks to his long interest in antiseptics and to his previous discovery of the natural antiseptic, lysozyme, Sir Alexander kept the plate for examination instead of throwing it away as many bacteriologists must have done before. The lapse of ten years between his discovery of penicillin and its preparation in a concentrated form suitable for therapeutic trial by the Oxford workers was due to the difficulty of concentrating and purifying it. This was a chemical problem. He himself was a bacteriologist.

It is calculated that pure penicillin, even if diluted to 1 in 50 million or more, will inhibit the growth of staphylococci, the common microbe of boils and carbuncles. On the other hand, it is so non-poisonous that, so far as Sir Alexander is aware, no one has yet had enough to poison a man. Like the sulphonamides, it is very specific, affecting certain microbes but having little or no action on others. It seems unlikely that we shall ever get an antiseptic which will affect all microbes without being poisonous to some human cells, but we shall have to arm ourselves with a series of chemicals covering the whole range of microbic growth. This will make it more difficult for the medical man; he will have to pay more attention to bacteriology than heretofore.

Penicillin is not perfect. For one thing, it is so rapidly destroyed in the stomach that it cannot be given by the mouth. There is still scope for the chemist to synthesize it, and then tinker with the molecule so that the imperfections can be remedied. There are thousands of other micro-organisms which may be capable of manufacturing even better antiseptics than penicillin, or ones which might give a clue to the chemical linkages responsible for the destruction of bacteria. The work is not finished—it is just beginning—and it is for the chemists now to carry it further.

## THE SCOTS PINE (*Pinus sylvestris*)

By ALEXANDER L. HOWARD

I remember, I remember,
The Fir-tree dark and high.
I used to think their slender tops
Were close against the sky.

THOMAS HOOD.

THIS tree, which is often incorrectly called 'fir' or 'Scotch fir', is a native of Britain, and the most important of our coniferous trees. From earliest days magnificent pine forests have grown in the Scottish Highlands where, as the Rev. C. A. Johns says, the seeds have been carried far and wide by the violent winds which are prevalent in that country, and also by rooks who are "Nature's planters of Pine Woods".

Gerard (1545–1612) speaks of these trees as

"growing in Cheshire, Staffordshire, and Lancashire where they grow in great plentie, as is reported before Noah's floud, but then being overflowed and overwhelmed, have been since in the mosses and waterie moorish grounds, very sound and fresh until this day; and so full of resinous substance that they burn like a torch or linke, and the inhabitants of those countries do call it Firre Wood and Fire woode unto this day."

Some people consider the Scots pine an uninteresting tree, and it is true that when reared under modern conditions in regular rows the conventional habit of its growth is apt to destroy its decorative value.

When planted with other trees it stands out conspicuously; but probably to appreciate its beauty to the full it should be seen as so many famous artists loved to paint it, in a group standing on high ground, thus outlined against the sky.

Under good conditions the Scots pine grows with great rapidity, reaching a height of about 100 ft., a clean bole of 70–80 ft., with a girth of 10–11 ft.

The bark is tough and fissured; the lower part of a dark reddish-brown, and the upper smoother and bright red. In early life the thick bushy foliage grows in pyramidal form flattening out later into tiers of irregular shape.

Johns tells us that in the Highlands of Scotland

"almost every district bears the trace of the vast forest with which at no very distant period, the hills and heaths were covered . . . on the South of Ben Nevis a large Pine forest . . . was burned to expel the wolves."

One wonders whether Robert Bridges had made a study of scientific forestry when he wrote:

"His spear, to equal which the tallest pine hewn on Norwegian hills . . . were but a wand."

However that may be, it is a fact that in Norway, Sweden, Finland and Russia the Scots pine has played the most important part in the economic history of these countries; especially in Russia has the subject received intense study, and been given every scientific assistance, but unfortunately the same cannot be said of Great Britain, with the exception of some effort since the establishment of the Forestry Commission.

It is not surprising, therefore, that the quality of British-grown pine has been found generally very inferior to that imported from these other countries. Whereas in the U.S.S.R. an excellent system of grading has been adopted, in most other places either little attention has been paid to the question, or conditions do not allow of much variation, for the general quality of the timber is fairly uniform, and up to now could not be classed in a high grade. The variation in England, however, is considerable, some districts producing excellent timber while others only poor quality.

Lord Sackville told me that one of his ancestors three hundred years ago brought from Memel Scots pine planks to provide floors for the long galleries at Knowle Park, Sevenoaks, as the trees growing on his own land, though abundant, were of poor quality.

In the time of Samuel Pepys, Scots pine was only imported in one dimension—three inches by nine inches and 12 ft. in length. These were termed 'deals' in England; other sizes were termed 'planks', 'battens' and 'scantlings'. Curiously enough, whereas the other terms were never adopted except for their real meaning, the word 'deal' became known to describe any kind of coniferous wood regardless of size, the name being still used wherever English is spoken.

Samuel Pepys, under date of October 18, 1664, records in his Diary:

"Thence to the Exchange, and so home to dinner, and then to my office, where a full board, and busy all the afternoon, and among other things made a great contract with Sir W. Warren for 40,000 deals Swinsound, at £3.17/– per hundred."

One hundred deals of similar character would cost to-day £69 17*s*. Swinsound was a port of Norway, about a mile from Fredrikshald, close to Frederikstadt, and now called Halden. The deals were hand-sawn and of superior quality. Norwegian imports, under the name of 'Christiania', continued, and the name 'Christiania deals' was still in use up to 1939. Probably the last shipment into England was in 1878, after which Norwegian supplies failed. From this time forward importations from Sweden, Finland and Russia increased in volume year by year; later supplies were received from Canada, America, southern Europe and Poland. All these revealed an ever-growing destruction of the larger trees. For several years after 1878 shipments consisted of more than 75 per cent of sizes 3 in. by 9 in. and larger, with only 25 per cent of smaller dimensions, but by the year 1939, except for the U.S.S.R., only 15–20 per cent could be obtained of the larger sizes. While with the Russian a better average of large sizes was maintained, not more than one piece in five was free of the centre, whereas in earlier years only one centre piece would be found with four or five quite free. Throughout, the inclusion of sap wood has greatly increased, and scantling sizes are almost all sap wood. The foregoing is a clear indication of the manner in which the forests are being exhausted.

In 1937–38 we expended the immense sum of £51 million on importations from Sweden, Norway, Finland, the U.S.S.R., Esthonia, Latvia, Lithuania, Poland, Yugoslavia and Rumania, the principal of which was Scots pine. This was used for joists, beams, rafters, flooring, etc., and the better qualities for joinery work, doors, window-frames, shelves and cupboards, etc. Prior to this War (1939) trees grown in Great Britain were used only for rough work such as gates and fences, and for estate purposes, but lately so great has been the demand that what was once considered inferior is now regarded of great value. Bearing in mind the vast building operations which will be necessary for many years after the War, Scots pine will be more than ever in demand, and should be planted freely in all suitable areas where the climate and soil are congenial, and reared on the most scientific principles of forestry, in order that the quality may be improved.

## PRINCIPLE AND PRACTICE IN VEGETATIVE PROPAGATION

PRACTICES of vegetative propagation of plants, originated in antiquity, and used without change for many centuries, have probably received a greater inspiration from modern science than any other of man's ancient occupations. The discovery of plant hormones made it possible to propagate species which had previously defied the greatest horticultural skill. There are, however, many other factors which have recently been passed in masterly review by R. J. Garner*.

Although the title of the pamphlet places special emphasis on pome and stone fruits, the work includes consideration of a wide variety of plant species, and certain generalizations are possible. New growth is a better source of cuttings than older material, and the presence of abundant stored carbohydrate food also assists this form of propagation. Indeed, soaking cuttings in sugar solution has often induced rooting. Lateral shoots are superior to terminals, and basal

* Imp. Bur. of Hort. and Plantation Crops. (Tech. Comm. No. 14.) Pp. 1–79. (I.A.B. Central Sales Branch, Agricultural Research Building, Penglais, Aberystwyth, Jan. 1944.) 3*s*. 6*d*. net.

cuttings root best. "The time of taking cuttings should be governed by the condition of the material rather than by the calendar." Various methods of application of synthetic hormone substances are described and, although these still give varying results, they represent by far the greatest single advance in technique. The effects of temperature, moisture and light form an interrelated complex, which should be determined for each species. Wound stimulation can increase rooting response; leaves are generally necessary, but flowers are a hindrance to regeneration.

Rooting media must be well aerated, but must also hold sufficient moisture; peat is considered to provide rooting stimulants, possibly of hormone nature. Some stem cuttings root better after an initial period of inversion, while some root cuttings regenerate better if the proximal end is above the compost. The presence of nitrogen hinders the rooting of normal plants, but nitrogen-starved growth may occasionally be stimulated to root by treatment with suitable nutrient solutions. Layering and marcotting (aerial layering) appear to depend for their full success upon some form of constriction or ringing which presumably increases the carbohydrate in the parts which are to root. Mr. Garner finally discusses the application of principles revealed by his survey to the practices of propagating fruit trees in use at the East Malling Research Station. Many orchards and nurseries are at present in bad condition because of the War, and Mr. Garner's publication has the objective aim of demonstrating the best methods for their restoration when peace returns.

## GROWTH OF CEREAL EMBRYOS

SINCE the pericarp in a cereal such as barley is semi-permeable, during the first period of germination the embryo is exposed to a low level of water and oxygen availability (0·1 atm.) and a relatively high carbon dioxide concentration (0·1 atm.) (R. Brown, *Ann. Bot.*, N.S., 93 and 275; 1943). In contrast, when excised embryos are being cultured, as in attempts to elucidate some of the problems of vernalization and kindred phenomena, the young plants are being started under conditions of high water and oxygen availability. Whether grown on water or culture solutions, such isolated embryos always show an immediate drop in dry weight, followed by a slower loss over at least the first twelve hours, suggesting a leaching effect followed by a rather higher rate of respiration than in the embryos of intact grains.

The change-over from a dormant embryo with dense non-vacuolate cells to a seedling in a fully active state seems to occupy about the first seventy-two hours, since after that time the water content remains constant. Although the food reserves in the endosperm are not available to the young plant during the first twenty-four hours of germination, excision within the first twelve hours of germination affects the linear and dry-weight growth, suggesting either that some substance is being absorbed (a hormone ?) or that the internal carbon dioxide concentration has a stimulating effect, either directly or by altering the acidity of the environment. When the carbon dioxide concentration is high, as in an intact grain, a low level of water-availability stimulates the linear and dry-weight growth of the embryo, either when attached or when growing on a nutritive medium. On the other hand, linear and dry-weight growth do not appear to be influenced by changes in oxygen concentration provided it is above about 15 per cent.

"Each of the factors considered above tends to be at a level inside the seed which, relative to the incident level of the same factor outside the seed, stimulates the subsequent growth of the seedling"; and there is probably "a high degree of instability in the metabolic pattern of the embryo . . . subject to modification according to the nature of the environment in which early development occurs".

## FORTHCOMING EVENTS

*(Meeting marked with an asterisk * is open to the public)*

### Saturday, November 25

ASSOCIATION FOR SCIENTIFIC PHOTOGRAPHY (joint meeting with the SCIENTIFIC AND TECHNICAL GROUP OF THE ROYAL PHOTOGRAPHIC SOCIETY) (at 16 Princes Gate, South Kensington, London, S.W.7), at 3 p.m.—Mr. G. Parr: "The Electron Microscope"; Dr. E. M. Crook, Miss F. M. L. Sheffield and Mr. L. V. Chilton: "Photographic Materials for use in the Electron Microscope"; Dr. D. G. Drummond: "Electron Micrography of Textiles".

### Monday, November 27

ROYAL SOCIETY OF ARTS (at John Adam Street, Adelphi, London, W.C.2), at 1.45 p.m.—Dr. S. J. Folley: "Milk", (2) "The Hormonal Control of Lactation" (Cantor Lecture).

ROYAL GEOGRAPHICAL SOCIETY (at Kensington Gore, South Kensington, London, S.W.7), at 5 p.m.—Mr. C. Hope Gill: "The Hadhramaut" (Kodachrome Film).

BRITISH INSTITUTION OF RADIO ENGINEERS (LONDON SECTION) (at the Institution of Structural Engineers, 11 Upper Belgrave Street, London, S.W.1), at 6 p.m.—Mr. E. R. Friedlander: "Magnetic Dust Cores".

INSTITUTION OF ELECTRICAL ENGINEERS (LONDON STUDENTS' SECTION) (at Savoy Place, Victoria Embankment, London, W.C.2), at 7 p.m.—Mr. W. A. Hatch: "Some Hydro-Electric Possibilities and Achievements".

IRON AND STEEL INSTITUTE (joint meeting with the SHEFFIELD BRANCH OF THE INSTITUTE OF BRITISH FOUNDRYMEN) (at the Royal Victoria Hotel, Sheffield), at 7 p.m.—Mr. B. Gray: "The Side Feeding of Steel Castings—a Note on the Influence of the Mechanism of Freezing".

### Tuesday, November 28

BRITISH PSYCHOLOGICAL SOCIETY (INDUSTRIAL SECTION) (at the National Institute of Industrial Psychology, Aldwych House, Aldwych, London, W.C.2), at 12.45 p.m.—Prof. E. A. Bott: "Some Problems of Selection and Training in War and in Peace" (followed by Questions and Discussion).

ROYAL ANTHROPOLOGICAL INSTITUTE (at the Royal Society, Burlington House, Piccadilly, London, W.1), at 1.30 p.m.—Prof. V. Gordon Childe: "Archæological Ages as Technological Stages" (Huxley Memorial Lecture).

INSTITUTION OF BRITISH AGRICULTURAL ENGINEERS (at the Institution of Electrical Engineers, Savoy Place, Victoria Embankment, London, W.C.2), at 2 p.m.—Mr. C. Culpin: "Machinery for Crop Cultivation".

CHADWICK LECTURE (at the Sir Edward Meyerstein Lecture Theatre, Westminster Hospital Medical School, 17 Horseferry Road, Westminster, London, S.W.1), at 2.30 p.m.—Mr. J. A. H. Brincker: "Research in all its Various Aspects Essential for the Promotion of Health and the Prevention of Disease" (Malcolm Morris Memorial Lecture).*

ROYAL INSTITUTION (at 21 Albemarle Street, Piccadilly, London, W.1), at 5.15 p.m.—Mr. F. C. Bawden: "Plant Viruses and Virus Diseases", (ii) "The Properties of Purified Plant Viruses".

ROYAL STATISTICAL SOCIETY (at the Royal Society of Arts, John Adam Street, Adelphi, London, W.C.2), at 5.15 p.m.—Sir William Elderton: "Cricket Scores and Some Skew Correlation Distributions (An Arithmetical Study)"; Mr. George H. Wood: "Cricket Scores and Geometrical Progression".

INSTITUTE OF PETROLEUM (at 26 Portland Place, London, W.1), at 5.30 p.m.—Reception to the Visiting Indian Scientists, when addresses will be given by Sir Shanti S. Bhatnagar, F.R.S., and Prof. J. N. Mukherjee.

INSTITUTION OF CIVIL ENGINEERS (at Great George Street, Westminster, London, S.W.1), at 5.30 p.m.—Mr. A. Shaw Maclaren: "The Design of Land Airports for Medium and Long Distance Civil Air Transport".

NORTH-EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS (in the Lecture Theatre of the Mining Institute, Newcastle-upon-Tyne), at 6 p.m.—Mr. E. Leslie Champness: "University Education in Shipbuilding and Naval Architecture".

SHEFFIELD METALLURGICAL ASSOCIATION (at 198 West Street, Sheffield 1), at 6.30 p.m.—Mr. H. O. Howson: "The Formation of Banded Structures in Centrifugal Casting".

### Wednesday, November 29

ROYAL SOCIETY OF ARTS (at John Adam Street, Adelphi, London, W.C.2), at 1.45 p.m.—Brigadier L. E. H. Whitby: "The Army Blood Transfusion Service".

BRITISH INSTITUTION OF RADIO ENGINEERS (MIDLANDS SECTION), (in the Latin Theatre, The University, Edmund Street, Birmingham), at 6 p.m.—Mr. G. F. Knewstub: "The Super-regenerative Detector"

INSTITUTE OF WELDING (at the Institution of Civil Engineers, Great George Street, Westminster, London, S.W.1), at 6 p.m.—Mr. M. Riddihough: "Hardsurfacing by Welding".

OIL AND COLOUR CHEMISTS' ASSOCIATION (at the Grand Hotel, Manchester), at 7 p.m.—Mr. G. A. Campbell and Dr. T. F. West: "DDT, the New Insecticide—a General Survey and some possible Paint Applications".

### Thursday, November 30

ROYAL INSTITUTION (at 21 Albemarle Street, Piccadilly, London, W.1), at 2.30 p.m.—Prof. James Gray, F.R.S.: "Locomotory Mechanisms in Vertebrate Animals", (ii) "Transition from Water to Land—Origin of the Limb with Five Digits, Its Development for Propulsion and Support".

INSTITUTION OF ELECTRICAL ENGINEERS (INSTALLATIONS SECTION) (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Discussion on (a) The Installation Section of the Report on "Electricity Supply, Distribution and Installation", and (b) The Report of the Electrical Installations Committee convened by the Institution on behalf of the Ministry of Works (to be opened by Mr. W. N. C. Clinch).

### Friday, December 1

ROYAL INSTITUTION (at 21 Albemarle Street, Piccadilly, London, W.1), at 6 p.m.—Prof. Herbert Dingle: "Spectrum Analysis".

INSTITUTION OF MECHANICAL ENGINEERS (at Storey's Gate, St. James's Park, London, S.W.1), at 5.30 p.m.—Mr. W. S. Graff-Baker: "Mechanical Engineering Problems of London Transport".

ROYAL ASTRONOMICAL SOCIETY (at Burlington House, Piccadilly, London, W.1), at 6.30 p.m.—Dr. G. C. McVittie: "The Spiral Nebulæ" (Lectures for the Forces, 1).

### Saturday, December 2

INSTITUTE OF PHYSICS (LONDON AND HOME COUNTIES' BRANCH) (at the Royal Institution, Albemarle Street, London, W.1), at 2 p.m.—Conference on "The Selection and Training of Personnel for Industry" (to be opened by Major F. A. Freeth, F.R.S.).

GEOLOGISTS' ASSOCIATION (at the Geological Society of London, Burlington House, Piccadilly, London, W.1), at 2.30 p.m.—Dr. G. M. Lees: "The Geology of the Oilfields of the Middle East".

SHEFFIELD METALLURGICAL ASSOCIATION (joint meeting with the IRON AND STEEL INSTITUTE and the SHEFFIELD SOCIETY OF ENGINEERS AND METALLURGISTS) (at the Royal Victoria Station Hotel, Sheffield), at 2.30 p.m.—Discussion of Papers presented to the Iron and Steel Institute.

## APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

VISITING PROFESSOR OF PHYSICS and VISITING PROFESSOR OF ORGANIC CHEMISTRY in the Farouk I University, Alexandria—The First Secretary, Royal Egyptian Embassy, 75 South Audley Street, London, W.1 (November 30).

ASSISTANT LECTURER IN ELECTRICAL ENGINEERING—The Registrar, College of Technology, Manchester 1 (November 30).

LECTURER (full-time) IN MECHANICAL ENGINEERING—The Principal, Battersea Polytechnic, Battersea, London, S.W.11 (November 30).

LECTURER (man or woman) IN MATHEMATICS—The Registrar, University College, Southampton (December 1).

LECTURER (full-time) IN MATHEMATICS in the Science Department—The Clerk to the Governors, South-East Essex Technical College and School of Art, Longbridge Road, Dagenham, Essex (December 4).

MECHANICAL ENGINEERS for the Government of Nigeria Public Works Department—The Ministry of Labour and National Service, Central (T. and S.) Register, Room 5/17, Sardinia Street, Kingsway, London, W.C.2 (quoting Reference No. C.K.2361.A) (December 5).

LOCATION ENGINEER by the Government of the Tanganyika Territory—The Ministry of Labour and National Service, Central (T. and S.) Register, Room 5/17, Sardinia Street, Kingsway, London, W.C.2 (quoting Reference No. E.1209.A) (December 5).

ENGINEERS (temporary staff) by the Government of Nigeria for the Public Works Department—The Ministry of Labour and National Service, Central (T. and S.) Register, Room 5/17, Sardinia Street, Kingsway, London, W.C.2 (quoting Reference No. E.1212A.) (December 5).

PHYSICISTS AND RADIO ENGINEERS for Hertfordshire Laboratory of large group of Companies engaged on Radio Telecommunications Research and Development Work—The Ministry of Labour and National Service, Room 432, Alexandra House, Kingsway, London, W.C.2 (quoting Reference No. A.631.XA) (December 5).

PSYCHOLOGIST AND EDUCATIONAL ADVISER (man or woman)—The Secretary, County Buildings, Shrewsbury (December 6).

RESEARCH BIOCHEMIST in the Department of Pathology in association with the Sheffield Radium Centre—The Registrar, The University, Sheffield (December 8).

ASSISTANT CHIEF ENGINEER in the Chief Engineer's Department—The Clerk of the London County Council, The County Hall, Westminster Bridge, London, S.E.1 (December 9).

LECTURER (full-time) IN MATHEMATICS in the Medway Technical College, Gillingham—The District Education Office, Kent Education Committee, Fort Pitt House, Rochester (December 9).

LECTURER IN AGRICULTURAL ECONOMICS—The Acting Registrar, The University, Leeds (December 9).

SPEECH THERAPISTS (two) in the Hertfordshire School Medical Services—The County Medical Officer, County Hall, Hertford (December 11).

ENGINEER AND MANAGER of the Plymouth Water Undertaking—The Town Clerk, Pounds House, Peverell, Plymouth (endorsed 'Water Engineer') (December 12).

ELECTRO-PLATING CHEMIST for appointment with an established West London manufacturing concern—The Ministry of Labour and National Service, Room 432, Alexandra House, Kingsway, London, W.C.2 (quoting Reference No. F.2409.XA) (December 20).

MATHEMATICAL PHYSICIST on the Staff of the Division of Radiophysics of the Council for Scientific and Industrial Research, Sydney—The Secretary, Australian Scientific Research Liaison Office, Australia House, Strand, London, W.C.2 (December 21).

LECTURER IN EXPERIMENTAL ZOOLOGY—The Registrar, The University, Liverpool (January 5).

LIBRARIANSHIP of the Bodleian Library—The Registrar, The University, Oxford (February 3).

RESEARCH CHEMIST, a RESEARCH ASSISTANT FOR MICROSCOPICAL DEPARTMENT, and one or more senior appointments and one junior appointment to the Liaison Department—The Director, British Leather Manufacturers' Research Association, 1–6 Nelson Square, London, S.E.1.

GRADUATE ASSISTANT MASTER qualified to teach Mathematics, Science and Engineering Drawing in the Junior Technical School and National Certificate Classes of the Ashton-under-Lyne Technical School—The Director of Education, 8 Warrington Street, Ashton-under-Lyne, Lancs.

TEACHER OF ENGINEERING DRAWING, with drawing office experience, in the Canterbury Technical Institute—The Director of Education, 78 London Road, Canterbury.

## REPORTS and other PUBLICATIONS

# POST-WAR FORESTRY IN GREAT BRITAIN

A LITTLE more than a year ago, the recommendations of H.M. Forestry Commissioners on the Post-War Forest Policy of Great Britain were reviewed in *Nature* (Sept. 25, 1943, p. 337). Their report (Cmd. 6447) was debated in both Houses in July 1943, receiving very general commendation and but little criticism. Meanwhile, the proposals have been receiving close attention from all who are especially interested in forestry, professionally or otherwise, and a good many reports and articles have appeared on the subject in newspapers and technical publications. Early this year, the Forestry Commissioners, after discussions with five of the leading societies interested in forestry, published a supplementary report on Private Woodlands (Cmd. 6500). A report on forestry policy has now been issued jointly by the Royal Scottish and Royal English Forestry Societies (Post-war Forestry, 1944)*, which include large numbers of woodland owners in their membership.

Though the figures for production of home-grown timber cannot yet be published, it is common knowledge that we have managed to meet the very large war-time demands for timber for all essential purposes despite very restricted imports. As the Forestry Commission has few plantations more than twenty years old, it is clear that private forests have had to shoulder by far the greater part of the burden, and the heavy demands on them are bound to continue for some considerable time yet. It can fairly be claimed, as it is in this report, that "in no other industry have the requirements of war-time so irretrievably destroyed the capital assets and the hope of profit for generations to come". Nearly a million acres of woodland in Britain will have been cleared in the two great wars of the present century. The rehabilitation of private woodland has accordingly a very strong claim to our most serious and early consideration.

In order to appreciate the proposals made in the Societies' report, it is necessary to recall the main features of the official policy that directly affect privately owned woodland. The first is the call for a considerable further increase of the total area under properly managed forest, the target being five million acres by the end of the next fifty years, with 1,100,000 acres to be planted in the first decade. This proposal has met with very general approval as both desirable and attainable, though the essential need for a stable policy and stable finance has everywhere been stressed.

The proposal then follows that, of the required five million acres, two million should come from privately owned woodland (which totals about three million acres in all), and a scheme for 'dedication' is put forward under which the owner undertakes: (i) to use the land in such a way that timber production is the main object; (ii) to work to a plan, to be approved by the forest authority, which would lay

* Post-War Forestry. A Report on Forest Policy prepared by the Royal Scottish Forestry Society and the Royal English Forestry Society. Pp. 62. (Roy. Scot. For. Soc., 8 Rutland Square, Edinburgh. Roy. Eng. For. Soc., 48 Dover Street, London, W.1, 1944.)

down the main operations to be undertaken; (iii) to employ skilled supervision; (iv) to keep adequate accounts.

In return for these undertakings, the owner will receive monetary grants which, after consultation, have been agreed at £7 10*s*. per acre planted and a maintenance grant of 2*s*. 6*d*. per annum for each acre of productive woodland for fifteen years, from the date of dedication or planting: these grants to be reviewed after five years, and loans to be available at the rate at which the forestry authority is financed. The originally proposed alternative of a refund of 25 per cent of net expenditure will remain open, and the owner will have to determine which alternative is the more advantageous to him—the relation between the extent and cost of the planting to be done and the value of the timber to be felled being the controlling factor. Many owners consider that the proposed grants are still inadequate, particularly that of 2*s*. 6*d*. per acre towards maintenance of young plantations, and this might well be doubled. It is also urged on good grounds that the grants should be free of income tax (unless taxed as a business under Schedule *D*). A further point to which attention is directed is that many woods felled during the War could not be cleaned up at the time and a grant should be made towards the cost of doing this prior to replanting: although a case can often be made out, it would obviously be necessary to find some means of doing justice to those who have managed to do the work notwithstanding difficulties.

The present report, however, makes a very strong case for the claim that the Forestry Commission has not encouraged private forestry to the extent that was contemplated in the report to which it largely owes its existence, namely, that of the Acland Committee of 1918, and that the new proposals do not appear likely to provide an adequate remedy. The Societies consider they have good grounds for their assertion that much that was called for has been left undone or has been done only half-heartedly, and that their own approaches have either been discouraged, or after eliciting some show of interest, have not resulted in any permanent improvement. They also now point out that the Forestry Commission seems to be content to take over a considerable part of the private woodland instead of viewing the extent of dedication as the measure of success, the alternative of transfer being a penalty, not an objective. It is for these reasons, and because they see in State forestry a very powerful competitor for markets and labour, that they are very insistent on the separation of State forests and estate woodlands at a high level of administration and control.

This difficult question of the post-war forest authority in Britain is perhaps the main subject of the Societies' report. The Commission's proposal is for its own maintenance in much the present form, though the possibility of its coming under a Minister (the Lord President of the Privy Council is suggested) is examined and some devolution of powers is suggested. For private woodlands, a special committee of the Commission is proposed, the two executive Commissioners (for England and Wales, and for Scotland respectively) having separate assistants for State forests and private woodland, and divisional officers—there are at present nine in England and Wales and four in Scotland—having separate staffs for the two types of forest ownership. Any such organization is quite unacceptable to the Societies voicing the owners' view, and they have put forward a plan of their own. The Commission, or Board, should consist of about twelve members under a nominated non-technical chairman. There would be four technical commissioners (paid officers, two for State forestry and two for estate woodland), five regional representatives (unpaid men of standing in forestry appointed after consultation with the forestry societies, two for England, two for Scotland and one for Wales), and representatives of the main political parties as at present. Further, there should be committees for England, Scotland and Wales respectively, including co-opted members. The present composition of the Forestry Commission is not such as could be expected to inspire foresters with confidence, and these proposals should remove some of the objections raised against the present arrangements. The question of Ministerial responsibility is discussed at length because it is difficult of solution: that it is desirable is agreed; but there are strong objections to giving that responsibility to the Ministry of Agriculture, and all are agreed that the administrative differences between Scotland and England must not be allowed to split responsibility for forestry, and with it the forestry authority itself. At the same time, very close liaison is essential between forestry and agriculture administrations.

A major point of difference between the views of the present Forestry Commission and the Royal Scottish and Royal English Forestry Societies is in the place and value of local executive committees with owner representation. The Commission repeats its view that unified control is necessary, and that advisory committees to the divisional officers are best calculated to secure the necessary contact with owners. The Societies—and it is clear that the considerable majority of owners and independent and informed critics are with them in this—are far from favourably impressed by the Commission's record in its relations with the various bodies set up with advisory or consultative functions; indeed, they consider that the War Agricultural Executive Committees have been successful enough to indicate that executive committees of a similar type should meet the special requirements of estate forestry equally well. They accordingly suggest the setting up of twenty to thirty regional forestry committees to collaborate with the same number of regional officers for estate woodlands, "advising and actively assisting them with regard to the prosecution of their duties" and "making recommendations for the expenditure of monies"; moreover, the committees are to "exert effective supervision over" the regional officers, who would work under the technical commissioners for estate woodlands, not under the conservators for national forests. It is also proposed to set up three central committees including representatives of these regional committees, and to provide

channels of appeal for both interests in case of disagreement. However, as it is recommended that each committee should at first consist of a part-time paid chairman, a vice-chairman and one other member appointed by the forestry authority, together with two members selected by the appropriate forestry society, and that its structure and powers should be reviewed after five years, it cannot be charged that it is desired to deprive the regional officer of the technical backing he must have if he is to carry on his work efficiently, but only to ensure that he is amply informed of local circumstances and opinion. The success of any such organization will depend very largely on the personalities concerned, and the result will consequently vary greatly from region to region: it is, however, worth a trial, on the understanding that considerable executive powers are assured to the regional officer.

A minor comment may here be interpolated in the form of an expression of the confident hope that the designation 'conservator' will be reserved for senior officers of administrative rank (with some twenty years service), as is the practice throughout the British Empire, and as indeed the Forestry Commission proposes to do in changing its present divisional officers to conservators. There should be no difficulty in finding suitable titles for the local officers.

Another of the Commissioners' proposals which has met with general disapproval is the deliberate withholding of help and encouragement in respect of small woods (limiting acreage undefined). The Commissioners have modified their proposals after discussion to the extent of agreeing that the standard planting grant of £7 10*s*. per acre should be payable on small woods, not being suitable for dedication (many will be suitable in company with larger woods), but the Societies consider that the rehabilitation and effective management of small woods in Britain, which comprise about one million acres, should be one of the main objectives in any national policy. They think that their own proposals, with regional officers and committees for estate woodlands, and particularly the active encouragement of co-operative organization, would accomplish this desirable end. The experience of the Scandinavian countries is quoted in support, and attention is directed to the fact that a small beginning has already been made in Britain despite the fact that the State assistance afforded to agricultural co-operatives is expressly withheld from forestry co-operatives—a position which should be amended in the expected new Forestry Act. This problem of the small woods is one which affects directly a very large number of owners, and indirectly almost the whole population, since it is these small woods in their tens of thousands which contribute one of the chief and treasured characteristics to the landscape of Britain.

Another matter on which public opinion is not satisfied is the supply of trained men, and the pay and prospects of those employed in forestry work, from the head woodman up to the higher personnel of the Forestry Commission. Perhaps the chief need is for more regular rates of pay for qualified head foresters and skilled head woodmen. To quote the report, there has been a "vicious circle of low or irregular rates of pay, a dearth of competent applicants, indifferent management and a belief that forestry cannot afford to pay an attractive wage". Shortage of rural housing has often worsened the position.

It is well known to foresters who have been faced with the problem of introducing planned management in previously unmanaged or mismanaged forests that progress is often determined more by the building up of an efficient technically trained staff than any other single factor. The Societies review the past and present facilities for meeting educational needs in forestry in Britain and find them extremely inadequate and far too exclusively devoted to training men for the State forests; they add some useful suggestions to those already put forward by the Forestry Commission.

Like almost every other informed critic, the Societies find the Forestry Commission's research programme totally inadequate in view of the general programme; how inadequate is perhaps best reflected by their comment that they would like to see the proposed allocation of funds trebled by the end of ten years. It may well be asked how anyone can, nowadays, in view of overwhelming evidence to the contrary, make the assertion that seed selection and tree breeding are not urgent matters when it is proposed to plant some 4½ million acres. It is probable that genetical work could best be done at a research station such as the John Innes Horticultural Institution to derive maximum benefit from existing knowledge and experience in the several highly specialized fields which together constitute genetics; but if the forestry authority does not stress the urgency of the work, contribute the special forestry point of view and facilities, and provide appropriate financial support, progress will be so slow that results will be obtained too late for the main opportunity for application, a position that has already prevailed in Britain far too long. A first step, one that could be taken immediately if belatedly, is to organize the selection of the best and most suitable stands of the important species, their reservation and tending for maximum seed production, and the collection, certification and distribution of seed from them, as is done in many Continental countries.

Then again, the economics of forestry, long neglected, should surely receive close attention and investigation in view of the proposal that the State should invest £41 million in the next ten years and should control private forestry as well. Forest management is closely linked up with economics and with land management generally, above all in estate forestry. The subject is not one which readily lends itself to the usual experimental research methods, but every wood the history of which is adequately recorded with costs constitutes in itself an economic experiment, and the research work to be done is a special comparative study of such experiments with the view of utilizing the results for better future management. The State proposes to scrutinize and approve the plans according to which dedicated woods are to be worked. What, it might

very well be asked, does the State forest staff know about the management of estate woodlands ? Granted they may now have more experience of large-scale plantation work in Britain than anyone else, but every professional forester knows that modern forest management is conspicuously absent from Britain, beginning with the Crown forests such as the New Forest and the Forest of Dean, while university instructors complain that they still have to take their students to the Continent to demonstrate the results of organized forest management.

Efficient management is to a very large extent conditional on the existence of adequate markets at prices yielding a margin over costs of production. Steps must accordingly be taken to develop markets for home-grown forest products, and to ensure that the State forests share them with estate woodlands. Markets for the large amounts of material of small dimensions available from thinnings in plantations are the chief need; in fact, it is hard to see how forestry can flourish without them. Possible measures to this end cannot be discussed here.

Opinion is perhaps not so unanimous as to the need for special research on forest engineering problems. Thus many take the view that the necessary vehicles needed for extraction of forest produce over rough, cheaply built roads have already been developed for war purposes, and that industry can be relied on to devise improvements in tools, etc., once the need is made clear.

A further question that arises here is the administration of forestry research. Opinion among foresters seems definitely that it would not benefit by being transferred from the forestry authority to the Agricultural Research Council; but that the present arrangement, under which the forestry authority consults a purely advisory committee, is unsatisfactory. The suggestion is that this committee should be strengthened by including greater representation of experienced foresters and by giving it much increased powers.

This review may be concluded on a note of warning. The need for a big extension and overall improvement of the practice of forestry in Great Britain is unquestionable: much of the work should have been done long ago and it behoves us to make up for lost time, but there is no field in which the motto *festina lente* is more appropriate than in forestry, where mistakes are likely to persist to mock one through several human generations. The Forestry Commission's new programme, commendable though it is in most of its items, flouts this motto in several respects. We have planted nearly half a million acres in the past twenty years, during which time we could without undue effort have won far more knowledge valuable for application to the next decade than we have. It is now proposed that we rush into a much bigger programme, and extend State control over private woodlands, not even allowing ourselves time to train the necessary personnel thoroughly. Surely the sound policy is to carry on at a more moderate rate within the competence of the available staff, and to put a considerable part of our new effort into research for application to our afforestation work. The ground that may be lost by proceeding cautiously during an initial period of thorough training and research, surveying and planning, can easily be made up by a later gradual planned expansion of the work, and its overall quality would certainly be considerably raised. The British Empire has established a high international reputation for its forestry work in India over the last seventy-five years: a start has been made in Great Britain, but our progress in all respects, except that of acreage under new plantations, has been so inadequate that we have if anything lost ground against the general advance. Let us make sure we do all in our power to start the coming post-war era on the best possible lines; and there is no aspect of British forestry which calls more insistently for improvement than estate forestry, so let us see that its special problems receive the attention which is their due.

## INTERPERSONAL RELATIONS IN EDUCATIONAL PRACTICE

The Social Psychology of Education
An Introduction and Guide to its Study. By Dr. C. M. Fleming. (International Library of Sociology and Social Reconstruction.) Pp. viii+110. (London: Kegan Paul and Co., Ltd., 1944.) 7*s*. 6*d*. net.

AN interesting trend in modern education is the declining concern with mere formal aspects of the mind, with attention, memory, reasoning, judgment and so forth. This has yielded to a new emphasis upon the child or pupil as a personality, as a social organism, as a member of diverse groups. The child's cognitive equipment is now seen in better perspective against his personal and home background, his emotions, attitudes, incentives and social orientation. Education ceases to be a study of rational faculties occasionally and accidentally disturbed by errors or by the vagaries of temperament. Perhaps the chief merit of Dr. Fleming's book lies in bringing home to the reader this change in education from being a cold, academic exercise to becoming a realistic guide in meeting the emotional, intellectual and social problems of the developing child and continually adjusting adult. Gently taking the teacher by the hand, Dr. Fleming leads him from his pedestal and shows him how to mingle easily among those he seeks to educate; the reciprocal influences between teacher and taught are now brought into fresh focus. The author's exposition is not, however, confined to the class-room. Wherever educative processes are discernible, at home, in office or factory, in clubs or institutions, the common principles of interpersonal relations are shown to be active between the educator and his charge.

Part 1 deals first with the deliberate or unwitting manœuvres and tactics, so to speak, which the teacher and pupils employ in establishing and maintaining their respective positions. This leads to a consideration of the modifiability of individuals and groups of which they are members, as a result of the mutual interaction between them. Part 2 traces the converging influences of family, community, school and other groups on the developing child. Part 3 (inappropriately called "Teachers are also Persons") is mainly concerned with the criteria of emotional maturity, and Part 4 with the treatment of educational failures.

Not only in Part 1 but also throughout the book, attention is rightly and repeatedly directed to the changeability of almost the whole range of conduct as contrasted with the limited number of traits the relative fixity of which is so often exaggerated in importance. A significant corollary follows. Selection for different kinds of schooling, and classification on the basis of aptitudes, are not ends in themselves but a means to better tuition and guidance. A clear distinction must be kept between the supposed limits of an individual's educability, on one hand, and the possibilities within those limits, on the other. Current test scores and mental ratios may provide some index of the former; they are of little use by themselves in regard to the latter. But it is precisely here that the educator's chief task lies.

The guiding principle in the book is the idea that the essential characteristic of behaviour is its specificity, due to the particular social and material circumstances in which it occurs. Traits of personality are therefore represented as relations rather than as qualities, that is, as functions of the interaction between the individual and his environment, not as inherent in the individual. For example, leadership —a topic to which Dr. Fleming gives some prominence —is conceived as a part which a person may play in a suitable situation, not as an intrinsic or general quality like intelligence or stature which he always has with him, so to speak, and displays on all occasions. On this theory, the same individual might take the lead as a matter of course in some situations and be content to follow in others. Differentiation into leader and led would be determined by the configuration of interpersonal relationships whether in class-room, playing-field, debating club, political gathering, military crisis or social emergency. This view involves a rejection of the notion, still favoured by some older academic psychologists in Great Britain, of conduct being relatively consistent, fixed and almost predetermined by a set of inborn propensities. Dr. Fleming also discounts the importance of general and type factors in personality, a departure from current teaching which it is not so easy to justify and which should be further explored. It is important to note that although the conception of general factors in personality, the conception, that is, of basic tendencies manifesting themselves in similar ways in diverse situations, owes its statistical development largely to those who think in terms of a framework of instincts, it does not necessarily stand or fall with the latter.

Quite a few of the author's views seem to be intuitive rather than objective in basis. The theory that leadership qualities are specific (p. 25) is a case in point, however plausible it may sound. Another instance is the statement (p. 18) that a basic need for personal independence manifests itself at an early age in the need for possessions. This is not in accord with reports of social anthropologists (for example, Margaret Mead), or with observations of infant behaviour generally. In observing very young infants, one cannot help being struck by the way they cast aside any object after the momentary attraction has passed. They are, in fact, incapable of a complex trait like possessiveness by virtue of their limited 'temporal span', if by possessiveness is implied awareness of ownership.

More care might have been taken in the chapter on "Family Influences". The observation (p. 41) that "the measured intelligence of children may differ *somewhat* [italics mine] from that of their parents" certainly does not convey the limited predictive efficiency of a coefficient of correlation of 0·5 between the test intelligence of mid-parent and child cited by the author in the previous paragraph. Precision is also lacking in the remark (p. 41), "about 80 per cent. of feeblemindedness has been attributed to inheritance", while the statement (p. 42), "all delinquents do not come of criminal ancestry", though logically sound, gives an exaggerated notion of the importance of heredity in view of the fact that the proportion of ascertained delinquency with criminal inheritance is probably in the region of 15 per cent. There is little justification for the following sweeping generalization about such a heterogeneous group as juvenile delinquents: "on the whole, the evidence is that children showing delinquent tendencies come from unwholesome homes and that their emotional maladjustments are accompanied by emotional maladjustments on the part of the parents" (p. 42). There is nothing in this statement to suggest that the author appreciates the "plurality of converging causes" (Burt) to which, as is widely accepted, delinquency is due.

Some passages have rather a casual air about them, particularly those dealing with growth (p. 62). What, for example, is the reader expected to make of the observation "prediction [of physical and mental growth], except for averages of groups, is extremely hazardous, and even that is hazardous during the period of adolescence"?

These minor criticisms should not, however, deter students and practitioners of education alike from reading this fresh and stimulating approach to the social aspects of their problems. JOHN COHEN.

# CHEMISTRY AND ATOMIC STRUCTURE

**Recent Advances in Physical and Inorganic Chemistry**
By Prof. Alfred W. Stewart and Dr. Cecil L. Wilson. Seventh edition. Pp. xii+512+5 plates. (London, New York and Toronto: Longmans, Green and Co., Ltd., 1944.) 28*s*. net.

IN an attempt to keep pace with the remarkable advances in physical and inorganic chemistry since the sixth edition of this useful work was published, Prof. Stewart has made some drastic changes which have greatly increased its value. Dr. C. L. Wilson has contributed eight new chapters and has revised the rest.

Our ideas on atomic structure have undergone considerable change during the interval. The discovery of deuterium introduced a novel feature, for we have in hydrogen and deuterium two isotopes which differ so widely in atomic mass that they act like different elements. Not only is there an entirely new range of compounds to examine, but also a serious revision of physical constants is involved. It has been shown that although the atom may give rise to quite a number of different particles, namely, protons, neutrons, deuterons, electrons, positrons, α-particles and mesons, each of which is discussed in turn, the present view is that the nucleus is composed only of protons and neutrons. The mechanism whereby the other sub-atomic particles are projected is still uncertain. The high voltages produced by the cyclotron have given us high-speed protons, deuterons and α-particles. Neutrons can now be obtained by bombarding beryllium with high-speed deuterons instead of α-particles. Since a neutron carries no charge, it

is not repulsed by the nucleus and has therefore great penetrating power. Fermi has shown that all the elements from 7 to 72, when bombarded with neutrons, give radioactive products, whereas only the first twenty are disintegrated by charged particles.

Isotopes with different radioactivities but alike in both charge and mass are rarely encountered among natural radioactive products but can now be produced artificially. The difference between these so-called nuclear isomers is one of energy content. Interesting examples are given by the bombardment of indium by fast neutrons. The rather complex results, which are not all radioactive products, are illustrated diagrammatically. The nucleus, which is at first excited to a higher energy-level by impact with the accelerated neutron, may return to the ground state by losing $\gamma$-radiation; but more frequently $\beta$-radiation is observed instead, the emitted electron being orbital and not nuclear. Theories of extra-nuclear electronic structure are discussed historically, and it is shown that the use of the four quantum numbers leads to a probable distribution of electrons.

X-ray diffraction has probably been the most powerful single physical method devised for the ultimate analysis of matter. It has laid bare the structures not only of the diamond, graphite and alloys, but also of textile fibres and other complex molecules, and it has clarified our views on valency. Robertson has achieved remarkable success in plotting electron densities as a series of contour lines with the aid of a Fourier analysis. Electrons can also be diffracted, and although they are much less penetrating than X-rays they are much more active photographically and are well suited for examining tarnish films on metals. Atomic linkages can be measured by electron diffraction; and by using the electron microscope, a description of which is given, it is possible to photograph particles which are only 30 A. in diameter.

The chapter on conductance gives a clear account of the gradual development of the theories of ionic behaviour. The anomalies of strong electrolytes are still not completely solved, but the theory of complete ionization even in the solid state probably rests on a sure foundation, since such compounds act in a fashion entirely consonant with what is known of their fine structure.

## AGRICULTURE IN URUGUAY

**Investigaciones Agronómicas**

Por Prof. Alberto Boerger. Tomo 1: Fundamentos de la Producción Vegetal. Pp. 758. Tomo 2: Genética; Fitotecnica Rioplatense. Pp. 1,043. Tomo 3: La Producción y el Hombre. Pp. 443. (Montevideo: A. Barreiro y Ramos S.A., 1943.) n.p.

THIS compendious work is difficult to appreciate. It is built around the investigations of the Uruguayan agricultural experiment station "La Estanzuela". The researches of this station are discussed in summary form in the text wherever they bear upon the general problems discussed; copious indexes and a full bibliography of the station's publications (commencing in 1912) are given. No complete chronicle or map of the station is supplied, and it is difficult to find a statement of its position. The book discusses many broad problems having a bearing on husbandry, including methods of investigation, laws of yield, mixed crops, autarky, and the system of Henry George; and sometimes gives unexpected information, such as a survey of the organization of plant genetical inquiry in the Argentine, Uruguay and the Brazilian province of Rio Grande do Sul.

The book supplies many climatological data, but is no general statistical digest, and only incidentally yields information about agronomic practice in Uruguay and adjoining regions. Thus, from the description of a trial of rate of sowing of linseed, the reader can deduce that the normal rate of sowing must be about 70 kgm. of seed per hectare. Several factors affecting yield of the more important crops are thus brought to light, but no explicit information about local practice is given. The most important problem of selection before the Uruguayan wheat industry is stated to arise from the need of finding varieties not markedly affected by the date of sowing—which means, in effect, that what is wanted is wheat which will grow independently of the peculiar vagaries of the climate. It is a heartening sign that this and some other problems are reviewed regionally—with respect to the La Plata basin—and not merely nationally.

The author's interests are frankly in crop problems, and he includes many references to the relation between crops and livestock; but it may not be unfair to point out that the information about soils is less thorough than is warranted by the connexion between soils and plant growth. The deficiencies of agricultural investigation in South America seem to be those of a 'prairie' country of extensive agriculture where any established crop will grow more or less well, so that the obvious problems are on the surface; it is relevant to note that erosion is attracting attention, but that nothing much has been done about it yet except talking and writing in such general terms as those of this book.

The work may perhaps be summed up as the expression of the experience of one of the older generation of experimenters, who not only reviews the work of his own station but also includes the salient features of many problems to the solution of which the station has not contributed. If the book is regarded as a pool of some South American thought, it is legitimate to ask what streams have contributed to it and what it reflects.

Several tributes are paid to the work of R. A. Fisher and the revolution which his school of mathematical statisticians has effected in experimental technique. Fisher's methods have been extensively used in Uruguay and the Argentine by G. J. Fischer and others, and the book gives full acknowledgment to Fischer's work at least in so far as it emanates from La Estanzuela; this may outweigh the fact that no very recent European work on mathematical statistics is quoted. No later edition of Sir John Russell's "Soil Conditions and Plant Growth" is mentioned than the Spanish version of the sixth edition (1934); and Russell's review of the Woburn experiments, issued in book form in England, is quoted from a German abstract. In general, it seems that the author is better acquainted with recent Continental work than with British. The apparent tendency to ignore recent British contributions to agricultural science seems to lie deeper than a purely war-time shortage of books and other means of communication of ideas; though, if that shortage persists, the insulation of South America from British cultural and scientific ideas may become more serious.

HUGH NICOL.

### The Journal of the Institute of Metals

Vol. 69, 1943. Edited by N. B. Vaughan. Pp. xxxvi+526+41 plates. (London: Institute of Metals, 1943.) n.p.

THE "Journal of the Institute of Metals" has acquired a very high reputation as a medium for the publication of the results of research upon the alloys of the non-ferrous metals. Despite the distractions of war, this reputation is thoroughly maintained in the volume under review. Starting off with a joint discussion with the Institute of Physics on the application of X-ray methods in the investigation of the equilibrium diagrams of metals, it contains some two dozen other papers on corrosion and surface protection, the structure of rolled aluminium and brass, spectrographic analysis, electron diffraction—the thirty-third May Lecture by Sir George Thomson—a thermodynamic study of the ageing of the copper-aluminium alloys by Prof. S. T. Konobeevski, of Moscow, together with many papers on the metallography of the light alloys of aluminium and magnesium.

It should by now be unnecessary to stress the fact that the high standard of the Institute's papers remains unaffected. Considering the difficulties of the times, this volume is a most creditable achievement, on which everyone concerned, and not least the editor, Mr. N. B. Vaughan, is to be highly congratulated.

F. C. THOMPSON.

### The Chemistry of Life

An Easy Outline of Biochemistry. By Dr. J. S. D. Bacon. (Thinker's Library, No. 103.) Pp. ix+118. (London: Watts and Co., Ltd., 1944.) 2s. 6d. net.

IT is a difficult task to write a book about a technical subject in non-technical language without floundering hopelessly in a mass of words. The author has overcome this by simply explaining these technical terms when they must be mentioned. The underlying idea is that biochemistry is the understanding and interpretation of living processes on the basis of chemical transformations which are capable of precise measurements. Recent methods used as tools by the biochemist, such as ultra-centrifugation, dialysis, electron microscopy, labelling with isotopes and respiration methods, are described. Mention is made of enzymes, hormones, evocators, genes, chemotherapy, viruses and bacteriophage. A useful feature is a glossary of technical terms, although it is doubtful whether understanding, for example, of the terms 'crystalloid' and 'purine' is increased by defining them respectively as "soluble substances of low molecular weight" and "a class of organic substances containing nitrogen with a characteristic molecular structure".

T. F. DIXON.

### Gérmen e Cultura

Por Prof. A. A. Mendes Corrêa. Pp. viii+234. (Pôrto: Instituto de Antropologia da Universidade do Pôrto, 1944.) n.p.

THE author would be the last person to claim that this volume contained new and important information. His aim has been rather to sit back and survey a number of problems and to give us his ideas generally: the articles included are, as it were, conversation pieces, some being on subjects of universal interest, others on matters of more particular importance to the Portuguese themselves and to their offspring in the New World. Such a series of conversation pieces, when composed by a scholar and humanist like the Director of the Institute of Anthropology of the University of Oporto, are always worth reading, and they will be found to be a useful antidote to the procession of single-track ideas generated by the overpowering pressure of the War. Portugal, it must always be remembered, is one of the few countries of Europe that has remained at peace.

The articles included in this volume are on various subjects and of different lengths. Most of them were delivered in the first instance as addresses to meetings of learned societies held in Portugal during the last few years. The title of the book is taken from that of one of the articles. Others deal with prehistory and history in Portugal, with the ethnology of Brazil, with the science of population, with methods of combating degenerative factors present in the Portuguese people, with half-breeds, with rhythm and culture, with the passage to sovereignty from bondage, etc. It is all somewhat general and philosophic, but none the less pleasant for that; a book well worth perusal by the fireside.

M. C. BURKITT.

### The Blood Pressure and its Disorders, including Angina Pectoris

By Dr. John Plesch. Pp. viii+149+5 plates. (London: Baillière, Tindall and Cox, 1944.) 15s. net.

DR. PLESCH divides his book into three parts. Part 1 contains a description of the principles and construction of an instrument which records the pressure changes within the brachial artery when this vessel is subjected to compression. The variations in the records obtained in different cardiac and peripheral vascular diseases are discussed. There is much useful clinical and physiological information in this part of the book, but the arrangement of the material makes it difficult to discover. As an additional instrument in the armamentarium of the cardiologist it is of considerable value, but it does not replace familiar and well-tried methods of diagnosis.

Part 2 is devoted to a discussion of the venous pressure and its variations in health and disease. This discussion covers a wide range and again contains many observations and hypotheses of interest to both clinician and physiologist.

Part 3 takes up the special condition known as angina pectoris, and discusses its pathology, physiology and treatment.

The book suffers much from the absence of a bibliography. Various authors are quoted in the text, but no references are given to their publications. The work of American and British investigators in the field of cardiology and vascular physiology receives scant attention.

### Metallurgical Abstracts (General and Non-Ferrous)

Vol. 10, 1943 (New Series). Edited by N. B. Vaughan. Pp. xii+523. (London: Institute of Metals, 1943.) n.p.

THE "Metallurgical Abstracts" of work which comes within its own sphere is by no means the least valuable part of the activities of the Institute of Metals. The subject index alone of the volume under review extends to thirty-eight double-column pages, an indication in itself of the thoroughness with which the work is done. It will suffice for all those who have known this series of abstracts in the past to say that the latest addition is in every way up to the usual standard.

# CHEMISTRY IN THE SERVICE OF MAN*

By Dr. E. F. ARMSTRONG, F.R.S.

CHEMISTRY is the science which has discovered how things are composed, what properties they have and how they will react. Chemistry not only tells all about natural substances but also enables us to make new products rivalling the natural products in utility. Some of these safeguard health, others provide clothing, propel motor-cars, do a thousand other things and promise much more in future.

The manufacture by chemical synthesis of thousands of tons of substances of use to man depends on the availability of large quantities of suitable raw materials. The chemist wishing to make carbon compounds, which are without exception made up of longer or shorter chains of carbon atoms joined one to the other, seeks to start as early in the series as possible, generally from substances containing only two carbon atoms represented thus — C — C — in his graphic formulæ.

To found a large-scale industry which is to handle many tens of thousands of tons, the raw material must be available in plenty and at world prices. It must bear no tax at this stage, a point largely overlooked by our politicians, or any other avoidable burden; in short, the price must be as low here in Britain as it is anywhere else in the world if the home industry is to be competitive.

The problem in making the large molecules or polymers composed of repeating units, which constitute many of the plastic materials, is to induce a large number of relatively small molecules to join together by chemical means. It would be a difficult and costly operation if we had to build the large molecule step by step; fortunately there is a trigger-like action between two carbon units at a high temperature, so that the energy set loose when they combine brings about a chain reaction in which perhaps a thousand units join together. The chemist has learned how to control the growth of the molecule so that the most suitable molecule-length may be obtained to suit the particular purpose for which the polymer is to be used.

The search for raw materials thus becomes one for two-carbon compounds; there are several alternative sources of these which it is proposed to examine here primarily in relation to their availability in Britain and the British Empire.

(1) Acetylene made by the action of water on calcium carbide, which in its turn is made from lime and coke by processes which need very large quantities of electric power: this power must necessarily be low-priced. In general such power, either in quantity or price, is not available in Britain, and it is not considered that any of the carbide production will be available for chemical synthesis.

(2) Two-carbon compounds made from alcohol by simple large-scale processes. Industrial alcohol is made by fermentation of carbohydrate materials, in particular from molasses which is imported in tank steamers just as is crude oil. It is recovered from the spent mash by distillation: other commercial products of the operation are carbon dioxide used to make 'dry ice' for refrigeration, and yeast. The formation of fermentable carbohydrates by plants is largely a function of the amount of sunlight—tropical countries have a great advantage over Britain in this respect. Our home cereals, required to feed man and beast, are too valuable to turn into alcohol except that limited quantity which is so profitably sold as potable spirits. The West Indian and other colonies need an outlet for their surplus carbohydrate material, and it is probable that industries can be developed there on the largest scale to produce material which can be easily transported to Britain for fermentation to alcohol.

(3) Two-carbon compounds made by the cracking of petroleum products. This industry is a modern adjunct to the refining industry which makes petrol, lubricating oils and burning oils.

(4) Two-carbon compounds made by catalytic synthesis from water gas and hydrogen. As water gas is made from coke, this is a simple form of oil from coal.

The oil-refining industry is only to a very minor extent established in Great Britain, since the discovery of a small native source of petroleum is a recent one. An increasing number of people consider its absence to be a very serious handicap, both because the country is deprived of these cracking products as the basis of the new chemical industry and because also the lack of this industry will mean the loss of incentive to our young men to become chemical engineers, of which more anon. The economic future of the synthetic, often called the Fischer Tropsch, process is still uncertain. It has been largely developed in Germany for military considerations.

Apparently if Britain is to develop these new synthetic chemical industries, the raw materials will be alcohol and/or cracking products. Both are being used to-day in America and there is the keenest competition between them, for example, as to which is the best raw material for the manufacture of synthetic rubber. Reports seem to indicate that the alcohol process is coming out well, which is of good augury for Great Britain where, as my analysis shows, it may be the most readily obtained raw material.

There is a great future for agriculture to supply raw materials, especially for chemical industry, sometimes called chemurgical materials. The sun and the rain and the soil enable man by the sweat of his brow to produce foodstuffs for man and beast. It is a wasteful process; too much depends on a variable market with manipulated prices, and much that is grown is left to decompose into simple products which return to the soil and the air. With cheap transport available and good organization, it should be possible to transform far more of what is grown into alcohol or protein and to lessen the waste. If this can be realized, great new employing industries can be set up in Britain and every yard of ground will be turned to account.

Lord Bledisloe has quoted with approval a statement "this nonsense world has too much chemistry, forgetting the living earth". Perhaps he is right in relation to farming, but reference is here made to the use of farm products as raw materials. In fact, there is need for more chemistry to help use the products of the farm, and we cannot do better than quote Mr. G. A. Sloan, president of the Nutrition Foundation:

"We think of cattle, corn, peanuts and soya beans primarily as food. In the future we will think of them also as sources of penicillin, synthetic fibres, hormones, vitamins, plastics and a host of new products which

* Extracts from the inaugural address to the Royal Society of Arts, delivered on November 1.

will increase the return to the farmers who raise them."

Some say we have not room to grow carbohydrates for alcohol in Britain, since we have only $1\frac{1}{4}$ acres per head of population. At least, we can avoid much waste, and there is the whole of the British Empire.

War experience has already taught that there is an economic use for all we grow when scarcity makes us take heed of our resources. Chickens, pigs, animal meat are not economic; milk production is! It is claimed, though not yet proved, that the yield of protein per acre in the form of yeast made from molasses calculated on the area of land required for the production of the molasses is several times greater than that of protein grown as soya beans, which have a high content of protein. It is also higher per acre than that obtained by feeding fodder crops to animals. In other words, 100 acres of sugar beet turned into molasses, turned into yeast would give more protein than 100 acres of grazing land turned into beef. These are the kind of sums which we may have to work out in the future.

The chemist has done much for food and will do increasingly more. There is an entirely proper prejudice in favour of fresh untreated foods; but we must, at least, know and understand everything about each one of them, and where the chemist can aid to make them safer to eat, more available, and guide their choice, his help should not be refused.

I wish here to direct attention to another phase of the food question, namely, that concerning proteins. Each protein is made up of a number of molecules of amino-acids, of which there are twenty different kinds. The protein molecules are very large, containing a thousand and more amino-acid molecules; they differ in the percentages of the various amino-acids present and may lack some of them altogether or contain the smallest quantities only. The individual amino-acids are joined end to end in a chain, the exact pattern of which has not yet been established for any protein; it is known to be constant for each particular protein.

The body breaks down the proteins, it eats into the individual amino-acids and uses these again to make its own protein: hence the importance of the individual amino-acids. Man and animals need most of them. Probably meat protein is so important a food because it contains those very amino-acids which we use to make muscle tissue. Nutrition experts are quite clear that a mixed diet is the best as a source of protein.

The scarcity, at least in war, and the cost of proteins make their economic production a matter of extreme importance. One main source is meat from animals, which convert vegetable protein in herbage into beef and mutton and pork; the process is a slow one. Another source is the pulses, seeds of high protein content which can be improved by selection and cultivation. Another source is fish.

The widespread cultivation of the soya bean is a notable example of progress in protein production. Unfortunately, this vegetable protein only ranks as second-class. Considerable interest, therefore, is attached to the production of protein in the form of yeast, which can be multiplied very rapidly in the course of a few hours. Whereas animals make their protein from the small amounts of organic vegetable protein in the very large quantities of herbage which they consume, the yeast cell is able to make its protein from ammonium salts, which are inorganic and manufactured from the nitrogen in the air. The technical question becomes whether yeast can be made in large quantity from carbohydrate material and inorganic nitrogen (ammonia) at a competitive price with meat. Inorganic nitrogen, a product of high-pressure technique, is to-day very cheap and available in unlimited quantity.

It is worth while giving some data about yeast production. They are based on U.S. experience. Baker's yeast is the chief yeast product; it is made to-day from carefully cultured strains having standardized activity in causing bread dough to rise in an appropriate number of minutes. Some 100,000 tons will be made in 1944. The vitamin content is not high, but it is possible to enhance it by changing the nutrient. Brewers' yeast is essentially a by-product of the fermentation of beer, and is not a raw material for another industry—more than 12,000 tons are available as a slurry, of which about one-third is recovered as cattle food and about one-tenth used as food or sold in the pharmacy. The vitamin content is some three times as great as that of bakers' yeast. The acceptance of brewers' yeast as food has led to the production in America of this type, grown especially for the yeast, that is, without hops, so that the product need not be debittered. The dried yeast has a high content of the vitamin B complex and retails for some 3*s*. a pound, a price which is reasonable on the basis of its protein content, which is about 46 per cent. A little calculation shows that yeast protein costs about 6*s*. 6*d*. per pound retail, whereas beef, with 19 per cent protein, selling at 2*s*. a pound, involves a protein cost of 11*s*. a pound. These figures are but an indication, but they are very suggestive of what can be done in the way of making protein quickly. Beef protein takes a year or more to make, yeast protein is a matter of twenty-four hours; beef certainly needs a larger acreage.

A specially suitable race of the yeast (*Torula utilis*) for the purpose has been recently developed in London, and factories are understood to be under construction to make it in Jamaica and Mauritius, where its first use will be for the under-nourished children in those Colonies. In the tropics, protein scarcity is often severe, but waste carbohydrates are plentiful. Certain races of yeast multiply so rapidly that the alcoholic fermentation is practically negligible. The yield of dried yeast in practice is 60 per cent of the fermentable sugar. It has been estimated in Germany that the waste sulphite liquors of the paper mills could make 100,000 tons of dry yeast a year, equivalent to 50,000 tons of protein. A development which is not very remote is the making of fermentable carbohydrates from wood. By what is known as the Scholler process, wood in presence of dilute sulphuric acid at a pressure of 4 atmospheres, the temperature being taken up to 190° C., is converted into easily fermentable glucose.

Largely within one generation, Britain and the United States have passed from a stage in which most of our food supply went directly from the farm to the consumer, to the present development in which the food industry processes and distributes a large and growing part of the total food supply. This could not have happened had it not been possible for the industry to do the job more efficiently, to provide better foods for the public at low cost. At first the development appeared to be on wrong lines from the point of view of optimum health, but the timely discovery of the importance of vitamins and the way to preserve and, indeed, obtain them has

altered this and made industry distribution of food of real benefit to mankind.

I would say a word about chemistry as a career. The nation needs many thousands of chemists, and the profession will attract an increasing number of young men. But the need is for enthusiasts with a real call to study and discover and make the furtherance of chemistry their life-work; those who think only that chemistry will give them an easy livelihood should be discouraged from entering the profession.

There will be countless opportunities in industry, in research and teaching, as well as in the professional branches of chemistry—the wise man will try to get experience in several of these before he settles down to his preference. While the material reward is important, and chemists, like others, must be properly paid, it is not everything, and many must be left free to pursue science for its own sake.

There is a tendency to place the utilitarian aspect of science too high, to associate universities, teachers and research with industrial development. This may have grave dangers if pursued too far; the universities must be left unfettered to pursue pure science, and endowed so as to make this possible. Their main function must remain to advance science for its own sake and they must avoid becoming tied to the wheel of commerce. "The wind of genius bloweth where it listeth."

In advocating the much more general teaching of science and scientific method throughout the schools, it is the scientific habit of thought that it is desired to cultivate, not mere scientific knowledge. The so-called practical man affects to despise theory, but he usually has a fairly intimate knowledge of his materials, gained by long experience, while if he is really practical, his methods are not far different from those of science. Where a knowledge of scientific method can help is in enabling new experiments to be devised which have a fair chance of success, or at least of teaching something. I have seen to my sorrow during this War far too many costly experiments made, the result of which a scientific man with knowledge could have easily predicted and which, therefore, were a waste of time and money.

The engineer, who is largely ruled by tradition, has intimate knowledge of the metals, but is being faced with the most varied requirements by industry for special plant to work at high temperatures and pressures, and to contain substances with corrosive and other unpleasant properties. To meet these difficulties a new class of engineer has arisen, the so-called chemical engineer, who supplements a sound general knowledge of engineering by a specialized knowledge of applied chemistry. There are degree courses at certain British universities for the training of such men. Actually, the country needs a great many more of them, perhaps several thousands, and the facilities for training them must be immediately increased.

I like to think of chemists as voyagers to a New World on uncharted seas of discovery, possessed of an Elizabethan quality as merchant adventurers. The Elizabethan age was one which had a soaring confidence; statesmen were not afraid to be something else as well—Bacon was alike man of science and philosopher. Science, industry, commerce, require art and skill to guide them; they need vitality for creative effort. It is our task to help to find them. It is not enough to search for true knowledge, for it is in the use of that knowledge we shall build our future.

The influence of war in accelerating scientific progress is often made the subject of comment. The reason for the greatly accelerated tempo is not far to seek—the needs are urgent, money is of no object, large-scale experiments are made possible, ample man-power is available. To Napoleon is credited the introduction of sugar beet in France to substitute for the West Indian sugar denied him by the blockade of the English Fleet; he also began the research which led to the preservation of foods by canning. This War has taken food preservation a stage further and developed the dehydration processing of food and much beside in the food industry: transport difficulties brought about by the submarine have forced these developments and produced a revolution, internal and external, in methods of transporting and preserving foodstuffs. Margarine was introduced during the 1870 War, but its development lagged until the War of 1914–18, and has been completed during this War, so as to put it on parity with butter. Perhaps the chief effect will be the great simplification of the problem of distributing food on a world-wide scale. Places and countries which are far distant, hard to reach and unhealthy, can now have normal healthy food supplies assured. Given also the advantages of refrigeration and air-conditioning, with power produced by the petrol engine, pioneering will lose half its terrors, while airports will become oases in the most savage lands.

Perhaps the person who is really encouraged by war is the technologist; hence the rather crude saying that science is useless until the technologist comes along and does something with the findings. Britain has made more than its quota contribution to discovery in pure research; it has largely left it to other nations to turn these discoveries to practical ends, and it is very slow to adopt them even when they are proved and of economic value.

It is comforting to read that even in the United States, where the speed of technical development is a cause for envy here, 'neophobia' exists, a term which means 'fear of the new' and that it may take ten or twenty years for a new product to become commercially successful. A wise friend of mine, H. A. Hopf, writes me that "every sensible person whose ideas are in advance of his times must have patience and persistence and a sense of humor".

It is claimed, and with a large degree of truth, that science, meaning the knowledge we have to-day in its various branches, has put those things which the individual wants, namely, food, work, security and freedom, within reach of all. The methods and ideas of science must become the dominant forms of thought and action in the future, but we must watch that talk is not substituted for action. Very few of those who offer Utopia to the public suggest that hard work will also be necessary and, indeed, must come first, if Utopia is to be earned. Forgotten is what Gilbert Cannan once expressed in "Pigs and Peacocks"—"laziness is the source of the whole trouble, letting the language, the traditions, the morals, the justice and the liberty of the race slip away"; there will be many who think this is just what is happening to-day.

It is widely advocated that the man of science and the engineer must exhibit depth and breadth of learning, and in particular see that the gifts of science are not wrongly used. The intention is good, but no man can control what others do with his inventions or their development. In fact, the developments during war, into which no question of econ-

omics is allowed to enter, are enormously greater and faster than they would have been during peace, and when peace comes mankind is assured of amazing benefits through them.

There is a hypothesis widely held by modern leaders of thought that the evolution of society, moving at an ever faster pace under the impetus given it by modern science, has up to now outstripped the capacity of human beings to adapt themselves. It is asked in the words of Herbert Read, "Is there a pattern or is it chaos; is it empty turmoil or is it progress?" That the world needs skill and vision to rebuild none will gainsay. Can we not say we are men of science and we believe we have the skill; we are artists and we believe we have the vision? Herein lies the future of this Royal Society of Arts. Shall we not repeat those Biblical words: "Be ye doers of the word and not hearers only, deceiving your own selves".

Perhaps then we may say with Shelley:

"The world's great age begins anew
The golden years return".

or with Carlyle: "Blessed is the man who has found his work—let him ask no further blessedness".

## THE BIOLOGY WAR COMMITTEE

THE Biology War Committee was formed more than two years ago with the object of establishing a clearing-house through which ideas or knowledge relating to war-time biological problems could be exchanged between biologists and the Government. In order to ensure the closest liaison and co-operation, the Committee was linked to a special Joint Committee of the Department of Scientific and Industrial Research, the Medical Research Council, and the Agricultural Research Council. Moreover, it was agreed that while the Biology War Committee should cover the main fields of biology, medicine should be excluded and that representation should be weighted in favour of those fields which were not highly specialized and in which workers were not already closely linked with the three Government research councils.

In the exploratory period following on its initiation, the Committee was concerned in organizing and also establishing contacts with both Government Departments and biologists. Attention was also given to discovering the types of biological problems most likely to arise under conditions of war.

During the last two years memoranda and reports on a variety of problems have been prepared, some at the request of the Joint Government Committee and many on the Committee's own initiative. In addition, many other suggestions, inquiries and problems have been considered. The Committee is not, however, in the position to make public any summary of its activities to date since, on the grounds of the national interest, the Joint Government Committee considers that references to specific problems would be inadvisable. The Biology War Committee can, therefore, only state that the range of problems touched on or investigated is remarkably wide. In several instances the solution has required collaboration not only between biologists of varied interests but also with other scientific workers. In fact the complexity of some biological problems, where only one link in the chain of causation may be concerned with living organisms, has obscured to non-biologists the realization that some war-time problems are in part biological. Again, lack of detailed knowledge has caused some confusion in assessing biological problems—for example, the tendency to group into broad categories and therefore a failure to distinguish between allied noxious and innocuous species.

When the original Committee, set up jointly by the Association of Applied Biologists, the British Ecological Society and the Society for Experimental Biology discussed the formation of the Biological War Committee with the Joint Government Committee, it was felt that the future Committee's usefulness would be enhanced if the composition was based solely on representation by subjects. The experience gained over the last two years has fully confirmed this view. At the same time, the Biology War Committee has been considering how best to ensure flexibility under the changing conditions of the War, and the need for maintaining close contact with biological societies.

With these ends in view, the Committee has been reviewing both its organization and its constitution. It has been decided that, as hitherto, much of the work can best be carried out by a small executive committee working in conjunction with sub-committees set up to deal with specific problems and with powers to co-opt members outside the Committee.

It has also been agreed that the membership of the full Committee should be reviewed annually and that before the final list of proposed members is settled, the list for the ensuing year should first be circulated to biological societies asking for their comments and suggestions as to the representation of subjects. In addition, it has also been resolved that two members of the executive committee, which includes the officers, should retire annually, and that only one member should be eligible for re-election. For the offices of chairman and vice-chairman, it has been decided that the tenure should not exceed one year, but that the secretary and treasurer should serve for three consecutive years.

After consultation with biological societies, the composition of the Biology War Committee for the ensuing twelve months is as follows: A. L. Bacharach; F. C. Bawden, Rothamsted Experimental Station, Harpenden; G. E. Blackman (*secretary*), Department of Botany, Imperial College of Science and Technology, London, S.W.7; Prof. P. A. Buxton*, Department of Medical Entomology, London School of Hygiene and Tropical Medicine; Prof. H. G. Champion (*vice-chairman*), Imperial Forestry Institute, Oxford; Prof. A. C. Chibnall, Department of Biochemistry, Cambridge; C. Elton, Bureau of Animal Population, Oxford; Prof. H. Munro Fox, Department of Zoology, Bedford College, London; Dr. W. P. K. Findlay, Forest Products Research Laboratory, Princes Risborough; Dr. H. Godwin*, Botany School, Cambridge; Dr. J. Hammond (*treasurer*), Animal Nutrition Research Institute, Cambridge; Prof. A. C. Hardy, Department of Natural History, Aberdeen; Dr. H. Martin*, Long Ashton Research Station, Bristol; Dr. K. Mather, John Innes Horticultural Institution, Merton, London; Dr. A. T. R. Mattick, National Institute for Research in Dairying, Shinfield, Nr. Reading; Prof. J. W. Munro, Department of Zoology and Applied Entomology, Imperial College of Science and Technology, S.W.7; Dr. J. Needham, Department of Biochemistry, Cambridge; Dr. F. C. Pantin* (*chairman*), Department of Zoology, Cambridge; Dr.

* Members of the Executive Committee.

O. W. Richards, Department of Zoology and Applied Entomology, Imperial College of Science and Technology, S.W.7; Dr. M. A. H. Tincker, The Laboratories, Royal Horticultural Society, Wisley; Prof. T. Wallace, Long Ashton Research Station, Bristol; Dr. E. B. Worthington, Freshwater Biological Association's Laboratory, Wray Castle; J. Z. Young, Department of Zoology, Oxford.

# OBITUARIES

## Prof. J. H. Priestley

PROF. JOSEPH HUBERT PRIESTLEY died at Leeds on October 31 at the age of sixty-one. He was born at Tewkesbury in 1883 and educated at Tewkesbury Grammar School (of which his father was headmaster) and at University College, Bristol. He was a graduate of the University of London and, in 1905, took charge of the Department of Botany at Bristol. In 1911 he succeeded V. H. Blackman as professor of botany in the University of Leeds. On the outbreak of war in 1914, he was in command of the University Officers' Training Corps and, as a captain, went to France with the B.E.F. During 1915–19 he served on the Staff (Intelligence), being twice mentioned in dispatches and awarded the Distinguished Service Order. In 1919 he became a Chevalier of the Crown of Belgium. After his return to Leeds, he built up a large and active botanical department there. He was a fellow of the Linnean Society and president of Section K (Botany) at the British Association meeting at York in 1932. He had for long served on the Forestry Commission, and also took a very great interest in the work of local naturalists, particularly of the Yorkshire Naturalists' Union, of which he was president in 1925.

Priestley was a man of such extreme vigour that it is not easy to give a balanced account of his activities. Quite apart from his service as a staff officer, he left his mark in each of three fields, as an administrator, as a teacher and as a botanist. To some extent, his work in each of these fields suffered from his continued and intense interest in the others, but the wider range of accomplishment was characteristic of the man.

At the time of his death, Priestley was the senior professor at Leeds, had long been a member of the Finance Committee and had served as pro-vice-chancellor for some four and a half years. His opinion on any matter of university administration was worthy of his long experience and profound interest. He had an almost equally long acquaintance with the work of the Joint Matriculation Board, of which he served as chairman; and as the head of a large department he could have had few, if any, equals. His powerful administrative judgment was based on mastery of detail, on great practical capacity and on a profound appreciation of the mentality of his fellow-men.

His botanical work started with the investigation, with F. L. Usher, of the role of the pigments in photosynthesis and the attempt to study their action *in vitro*. He was, however, chiefly interested in problems of growth, and, coming under the philosophical influence of W. H. Lang, became with characteristic enthusiasm a keen student of developmental morphology and anatomy. His preoccupation was with the organism as a living entity, and his studies of cell wall structures were intended to emphasize the view that the composition of these structures reflects the growth activities of the cells that formed them. With his great practical gifts, it was natural that Priestley should also be interested in the practical bearing of his scientific work, and he devoted much time to subjects like the influence of electricity on field crops, the propagation of plants by cuttings (Master's Lecture to the Royal Horticultural Society, 1925) and, finally, spiral grain in timber. His later work focused attention particularly on the properties of growing cells and tissues, on development in monocotyledons and on cambial activity in trees. The purpose of his work was to show that the form and structure of an organ reflects the "organisation of growth" in the tissue which formed it.

No doubt views will differ on the question of whether Priestley's success as a teacher was greater or less than that as an investigator. He was certainly a born teacher and the impact on his students of his powerful and vigorous personality was tremendous. Those who were going to teach science must have profited enormously by acquaintance with his methods, which always focused attention upon the fundamentals of the subject under review. The gift for seizing the main point at issue was certainly an outstanding feature of Priestley's character and it ran through all his work, administrative, educational and scientific. Combined as it was with never-failing courage, boyish enthusiasm and outstanding vigour, it made him sometimes didactic, often provocative, always interesting and, as a whole, one of the most colourful persons in biology.

W. H. PEARSALL.

IN the death of Prof. J. H. Priestley the botanical world and the Department of Botany of the University of Leeds have lost a man of originality and genius. Though cut off from fulfilling the period of university service to the usual age of retirement, his life has been a full one, and the record of his achievements is one of which any man might be proud.

As an undergraduate at Bristol, though primarily a student of botany, Priestley also attended the honours courses in chemistry and physics, a training which gave him an exceptionally sound basis upon which to found his botanical studies. At the close of his studentship, at the early age of twenty-two, his gift for leadership was recognized and he was deemed worthy to take charge of the Department of Botany in University College, Bristol. Coming into botanical science at a time when many botanists had been absorbed in confirming and amplifying the great discoveries of the late nineteenth century, he brought to botany an alert mind and a fresh outlook, which undoubtedly owed much to his sound knowledge of the pure sciences. One of his first lines of investigation was an attempt to ascertain the first product of photosynthesis, but later his interests turned more and more towards developmental and causal studies; in this new line of attack on plant problems he often turned for advice and encouragement to Prof. W. H. Lang, of Manchester, of whose work and judgment he held a very high opinion. The results of his studies along these original lines, with the complementary teleological work of Haberlandt and his school, gave to botany a much more satisfying understanding of many plant structures. His last and most outstanding phase of research dealt with problems of tree growth; he was much absorbed in the dynamic problems of

cambial activity and vessel differentiation, and his connexion with the Forestry Commission gave him opportunities to apply his knowledge to problems of afforestation.

Priestley had an exceptional knowledge of the literature and a memory for recorded detail with a capacity to fit together such scattered pieces to give a picture of his problem as a whole, where each detail fell into its right place and assumed its right value. He was himself often the first to admit that suggested interpretations of certain new lines of investigation had found their way into print prematurely, but even in such cases the interest aroused stimulated such vigorous work on the subject in question, to prove or disprove his theories, that botanical science had much to gain. The recorded facts upon which his theories were based were always sound.

Throughout his long service to science, perhaps his outstanding merits, which will long outlive him in the work of his students, have been the inspiration for research, the importance he placed upon true recording of facts and soundly based and courageous attempts to interpret them. In his teaching he maintained a freshness of outlook by the continual introduction of new methods and facts, which, from his great fund of knowledge, he selected to illumine aspects of subjects which students previously thought they had fully assimilated.

L. I. SCOTT.
R. D. PRESTON.

## Dr. Thomas Swinden

THE death of Dr. Thomas Swinden on October 27 at the age of only fifty-eight has deprived the steel industry of one of its ablest leaders, who during the past year had been playing an important part in the reorganization of research in iron and steel, and whose further help in that field would have been invaluable.

Dr. Swinden was born in Sheffield on August 15, 1886, and studied in the University of that city, being Mappin Medallist in 1905. During 1906–8 he held an 1851 Exhibition Scholarship, studying metallurgy at Stockholm and Uppsala. During 1909–13 he worked as a Carnegie Research Scholar, and was awarded the Carnegie Gold Medal. In 1913 he also obtained the degree of D.Met.

From 1909 Dr. Swinden was chief metallurgist to Samuel Fox and Co. of Stocksbridge, and was later works manager and director, but in 1932 he took up the important post of director of research in the United Steel Companies, Ltd., of which Samuel Fox had become an associate company. In this capacity he built up a remarkable research organization, with an able staff and well-equipped laboratories. Many valuable contributions have been made from this centre, both to metallurgy proper and to the study of refractory materials.

Besides controlling and guiding the research work of a large industrial concern and directing its application in practice, Dr. Swinden interested himself from the beginning in co-operative research for the whole of the iron and steel industry, and was one of the most active members of the committees and sub-committees set up jointly by the Iron and Steel Institute and the Iron and Steel Federation. Within the last few months he had assumed the chairmanship of several of these in succession to the late Dr. W. H. Hatfield, and he was an indefatigable worker for those committees. As a member of the Council of the British Iron and Steel Research Association which has recently been formed to take control of this work, he would have had many responsibilities in this field. During the War he took a leading part in the work of the Technical Advisory Committee on Alloy Steels, and was a member of the metallurgical mission to the United States in 1943, which imposed a considerable strain on those who took part in it.

Swinden's early papers dealt with the constitution and properties of the tungsten and molybdenum steels, and came at a time when there was very little information on such complex alloy systems. Later, he was responsible for much of the progress made in the production and use of steels with controlled grain size, and in recent years he and his collaborators did excellent work on the relations between carbon, oxygen and nitrogen in steel, making many improvements in the methods for estimating those elements, and making a special study of the low-carbon steels of the 'rimming' type.

Swinden was the most pleasant and courteous of colleagues. Very modest himself, he always gave full credit to his fellow-workers in his published work. His judgment on any disputed point was invariably trusted, on account of his wide practical experience and sound scientific knowledge. He was a faithful member of the Iron and Steel Institute, of which he had recently become a vice-president. He had received its Bessemer Gold Medal in 1941, as well as medals from the North East Coast Institution of Engineers and Shipbuilders and the Institution of Marine Engineers.

Always a hard worker, Dr. Swinden was found to be suffering from overstrain in the spring of this year and was compelled to take a rest. He had, however, apparently made a good recovery and had resumed much of his work, so his sudden death came as a shock. He had a happy married life, and leaves a widow and two sons to mourn his loss.

C. H. DESCH.

## Dr. Paul Ostern

DR. PAUL OSTERN was killed by the Nazis in Lwow at the beginning of July 1941, during a pogrom in which several men of science, scholars, physicians and others died. Ostern is well known to biochemists all over the world: although young, he made brilliant contributions to biochemistry. Born in Zloczow in 1902, he studied medicine in Lwow, and joined my staff in 1927. Ostern was especially gifted for chemical work. Though he received no special chemical training, except in my biochemical laboratory, he was able to cope with the most difficult chemical investigations. It was he who succeeded in obtaining on a large scale not only inosinic acid from muscle but also adenylic acid: during the nineteen-thirties every laboratory which was using adenylic acid for research purposes acquired it, directly or indirectly, from the Laokoon factory in Lwow, where Ostern was collaborating, and where the preparation of adenylic acid from fresh meat was under his supervision. Only in 1937 this changed, when Ostern made his brilliant discovery of enzymatic synthesis of adenylic acid from adenosin and phosphate, the method now generally employed for the production of adenylic acid—also for therapeutic purposes.

After his first research work concerning the formation of ammonia in the heart and the transformations of adenylic acid in this tissue, Ostern spent some time abroad, where his work with Krebs in Freiburg

was interrupted by the Nazi seizure of power and Krebs leaving that country; with Verzar in Basel, and then with Krebs again, in Cambridge. In Lwow he participated in the team work, with myself and Dr. T. Mann, now in Cambridge, which led to the discovery of direct enzymatic transfer of the phosphate group from phosphoglyceric to adenylic acid, with the formation of adenosintriphosphoric acid, and to the chart of the linkage of chemical transformation in glycogenolysis, as now generally accepted. With T. Baranowski and J. Reis (now in the British Eighth Army), Ostern discovered (1935) the direct transfer of phosphate from adenosintriphosphoric acid to creatine, and the role of the phosphocreatine-creatine system as an alternating acceptor and donor of phosphate was disclosed; in 1936 he discovered that Harden-Young fructose-diphosphate is formed from the monoesters and adenosintriphosphoric acid, and this very important link in glycogenolysis and glycolysis, the inhibition of which by oxidizing agents, as recently found by Engelhardt, is the essential factor of the Pasteur effect, was discovered by Ostern and his associates. His last important discovery was made, with E. Holmes and D. Herbert, in 1939, during a short stay in Cambridge—that glucose is formed in the liver by way of phosphorolysis of glycogen and subsequent hydrolysis of the phosphoric ester. The formation of glycogen from the Cori ester by liver enzymes was then published by these workers, simultaneously with the St. Louis group.

In 1940 Ostern was appointed professor of organic chemistry in the Medical School in Lwow. Unfortunately, he did not leave the city when the Germans approached. His many friends abroad will deeply regret the untimely death of this outstanding scientific worker. J. K. PARNAS.

## Prof. Forsyth James Wilson

PROF. F. J. WILSON, Freeland professor of chemistry in the Royal Technical College, Glasgow, died suddenly on October 18. For the long period of thirty-eight years he had been associated with the College which he served faithfully and well; his first appointment was that of chief assistant to Prof. G. G. Henderson. During the period 1914–19 he served in the Army, ultimately as chemical adviser to the Eleventh Army Corps. On more than one occasion he was mentioned in dispatches.

In 1919 Wilson returned to the College to fill the chair of inorganic and analytical chemistry. On the transfer of Prof. I. M. Heilbron to the University of Liverpool, he succeeded, at his own request, to the chair of organic chemistry, and held that until the death of Prof. R. M. Caven, when the two chairs were amalgamated in the Freeland Chair. This is good evidence of his breadth of knowledge of the subject.

Born at Moffat in 1880, Dr. Wilson received his earlier training at the University of Edinburgh, from which he passed after a distinguished record to Leipzig, being associated there with Hantsch and Stobbe. On returning to Great Britain he joined Prof. A. G. Green at Leeds in research on dyestuffs.

In Glasgow, he took a lively interest in all the local sections of the various chemical societies and at different intervals acted as chairman. He was meticulous in his attendance at meetings, and his general bearing in discussion was always courteous. In due course he served on the councils of the Chemical Society and the Royal Institute of Chemistry, and held office for more than one period in each case. Nearest to his heart was perhaps the British Association, and he rarely missed a meeting of the Chemistry Section.

In the limited time available from heavy official and teaching duties, Wilson was actively engaged on research in organic chemistry, collaborating with many colleagues, among them Stobbe, Boon, Heilbron, and more recently with members of the present staff of the College, Sutherland, Hopper, Crawford, McLean, and others. His research work was mainly devoted to a study of stereoisomerism with special reference to derivatives of semicarbazide and thiosemicarbazide, and to the resolution of optically active compounds derived therefrom. Latterly, he developed a special interest in certain aspects of chemotherapy, and in this connexion was associated with Imperial Chemical Industries Ltd. He was a frequent contributor to the *Journal of the Chemical Society*. With Prof. Heilbron he published a very useful little book on "Chemical Theory and Calculations"; although now out of print, it earned well-deserved popularity among a wide circle of students some twenty years ago.

Wilson's work in and for the Royal Technical College, Glasgow, met with unqualified approval and success, and his influence upon his students as well as his personal relations with them were admirable. Many of them holding important positions throughout the world will recall with pleasure his warm personal interest in their well-being, both during and after college days. Of shy and retiring disposition, he was a man of considerable grace and charm, highly respected and esteemed by his colleagues, no less than by his students. W. M. CUMMING.

## Dr. Henry J. S. Sand

DR. HENRY J. S. SAND died, after a short illness, at Nottingham on October 18. He will be remembered as an electrochemist of international repute, and he had also published outstanding original work in other branches of chemistry.

Dr. Sand was born in Dundee on December 7, 1873. He received his early education at the High School, Dundee, and later at the Realgymnasium in Dresden. It was during these early years in Germany that the foundations were laid of his excellent knowledge of the German language. For a short time he studied under Hempel at the Dresden Polytechnic, and then continued his university career at Zurich, where his inaugural dissertation was published in 1898. Here he worked under Bamberger, studying organic chemistry, and was awarded the degree of Ph.D. Upon his return to England, Dr. Sand worked with Ramsay at University College, London, for a short period and then, as a holder of a Bowen Research Scholarship at the University of Birmingham during 1899–1901, commenced the studies in electrochemistry for which he is so well known.

In 1901 Dr. Sand took up the post of lecturer and demonstrator under Prof. Kipping at University College, Nottingham, and continued his researches. He was awarded the degree of D.Sc. at Birmingham in 1905. In 1914 he moved to London and held the post of senior lecturer in chemistry at the Sir John Cass Technical Institute, London, until 1921, after which date until he retired in 1938 he was head of the Department of Inorganic and Physical Chemistry.

Sand's published scientific work is contained in about fifty original papers with subjects varying in scope from laboratory apparatus of his own design and construction to theoretical discussions in thermodynamics. He was thus both an able and skilled experimenter and a thinker of wide scientific outlook. Outstanding among his original investigations are the work on electrode processes including diffusion at electrodes and over-voltage, the development of vacuum-tight seals for leading in wires to silica and glass vessels, and various improved methods of electrochemical analysis. Particularly among these should be mentioned the separation of metals by control of electrode potential and the use of 'internal' electrolysis for determination of metallic elements in the presence of larger quantities of less noble metals. In 1939, 1940 and 1941 there were published successively the three volumes of his "Electrochemistry and Electrochemical Analysis", a work upon which he had spent many years of thought and labour and which summarized the state of electrochemical knowledge to that date.

To those who had the privilege of knowing him, Dr. Sand was a most amiable man. His former colleagues and research students particularly will remember his tolerant and kindly criticism, his balanced judgment and his unfailing help, which he gave freely to all those who brought their problems before him. He will be remembered and missed by many friends all over the world, and they will think with sympathy of his widow, and his only son who is now serving with the British Army overseas.

ARTHUR J. LINDSEY.

---

WE regret to announce the following deaths:

Sir Joseph Arkwright, F.R.S., honorary bacteriologist at the Lister Institute, on November 22, aged eighty years.

Prof. Charles F. Park, emeritus professor of mechanical engineering at the Massachusetts Institute of Technology, director of the Lowell Institute School, on September 25, aged seventy-five years.

---

# NEWS and VIEWS

## *The Times* and Freedom of the Press

How often do readers notice the serial number at the front of a journal? Yet this number is much more than a convenient means of identification used by publishers and printers; as is pointed out in an article in *The Times* of November 25, it indicates the intention of continuing to produce the journal at short intervals, so that the reader can follow the progress of events—it is a sign of continuous and watchful activity. *The Times* has given this service to Great Britain for the past century and a half, and it has now proudly inscribed the number 50,000 on the front page of its issue of November 25. As the years have gone by, *The Times* has grown in stature, under a succession of distinguished editors, until it is now an organ of international repute.

The leading article of the 50,000th issue rightly ends on the note of the freedom of the Press. One of the first acts of an authoritarian regime is to suppress the expression of contrary views; government by consent of the people, the very essence of democracy, requires a free Press, able to reflect and to guide public opinion. In times of war, a democracy must accept, however grudgingly, a considerable measure of dictation, including censorship of the Press. This suppression of facts in the interests of national security is an evil necessity under which every member of a democracy must chafe; particularly is this restriction of publication felt in scientific circles, where the free interchange of news and views is the life-blood of progress. *The Times*, with other journals, has accepted the necessity of censorship, but it declares in no uncertain terms its policy for the future: "As the war draws to an end and the shadow of military necessity recedes, the immediate task will be to ensure that every encroachment of authority shall be rolled back from a field of responsibility in which, in a free community, it can have no place". It will have the support of all who value democracy in carrying out this policy in the years to come.

## Communities and Industry

THE broadsheet "Location of Employment" issued by Political and Economic Planning is a timely contribution to the discussion of the fundamental questions in town and country planning on which early decisions must now be taken by the Government. The broadsheet attempts first to analyse the employment needs which are relevant to physical planning, and then considers how far those needs could be met on the scale of a community comprising not more than about 60,000 people. The conclusion is reached that a satisfactory variety of industry and occupation can usually only be provided for a group of communities, and not, as town-planners have often suggested, for each community separately. The important concept is not so much that of the community as that of the employment orbit, or the area in which any point can be reached within reasonable daily travelling time by the members of the community. For some communities it may be far better to improve communications with other places than to try to bring industry within the borders of the community. It should be possible for the majority of wage-earners to find work fairly near to their homes; many jobs in secondary and tertiary industries can be located in the community itself, and the broadsheet points out that the employment exchanges, by the use of judicious and flexible placing methods, can help in this. Secondly, the time taken up in travelling to work can be cut down by improving transport and by careful layout and correlation of the several communities.

Even when communities have been grouped in this way for purposes of employment, there may still be some which have no economic future by themselves and are so isolated that they cannot be combined in a larger region. Such communities, *Planning* considers, should be closed down. Again, the employment orbits suggested may not be suitable units for the industrialist. The advantages he requires may not always be provided therein; but it should be

possible to provide them in a region containing a number of such orbits. If there is movement of population from the congested cities, the 'overspill' is likely to be better accommodated and better employed if it is kept in close relation to a regional or sub-regional centre than if it is dispersed to independent new towns. Industrial development should be viewed on a regional scale, taking fully into account the existence of the traditional regions, and aiming at introducing new complexes of industry into these existing regions. The broadsheet points to several factors which increase the mobility of industry, but finally emphasizes the difficulty of applying the general principles indicated. Usually, in practice, the decision must be a balance between economic and social considerations, and close co-operation between the central Government and industrialists is needed.

### Selection of Medical Students

IN an earlier issue (*Nature*, **154**, 315, Sept. 9, 1944) the possibility that intelligence tests might be used as aids in the selection of candidates who wish to undergo a medical training was discussed in relation to the proposals of the Goodenough Committee on Medical Schools and the Planning Committee of the Royal College of Physicians for the selection of medical students by personal interview rather than by examinations alone. Drs. O. G. Edholm and Q. H. Gibson (*The Lancet*, 294, Aug. 26, 1944) have now published the results of their work on examination results as intelligence tests. This work was done at Queen's University, Belfast, where second-year medical students have, for the past three years, carried out "an intelligence test, using Raven's Progressive Matrices" (J. C. Raven, Progressive Matrices, London, 1938). The scores obtained were compared with examination results. The students included 20 per cent women, and the average age of both men and women students was 19½ years. These authors conclude that "one of the most striking and important points which emerges from these results is the high mental ability of the average medical student, as measured by the matrix test". They quote the report of the Planning Committee of the Royal College of Physicians as saying that the average medical student of to-day is lacking in initiative and curiosity, with poor ability to arrange and interpret facts and little precision in the use of words. "If we accept this statement," these authors comment, "either unusually great ability is necessary to avoid these faults, or they are not primarily due to any lack of intelligence." Other critics of the mental ability of the average medical student might take this statement to heart.

More pertinent to the selection of future medical students is the conclusion of Drs. Edholm and Gibson that "a fairly rigid process of selection has already been applied by the time the student reaches his second year". This would seem to confirm the view expressed in *Nature* (*loc. cit.*) that "Selection can . . . be imposed too early, and the value of the natural selection of the medical school and the hospital can be underestimated". Discussing the question whether the matrix test would be valuable for the selection of medical students, these authors conclude that the results of previous examinations form a more reliable index of results in future ones. They find no reason to think that the medical students of Queen's University are not representative of the intelligence of medical students generally; but they think that further work should be done to show whether their results are generally applicable. R. G. Inkster (*Roy. Acad. Med., Ireland*, Sect. Anat. and Physiol., March Meeting, 1944) obtained results similar to theirs; but he used an entirely different intelligence test. The authors do not wish to imply, however, that success in examinations is the only criterion of the satisfactory student.

### Spectrographic Discussion Group

THE Spectrographic Discussion Group was formed in 1941 as a result of approaches made to the various users of spectrographic equipment in the Glasgow area. It was considered that, in view of the extent to which industrial concerns and Government departments were applying spectrographic methods of analysis and the very rapid developments which were taking place in this branch of science, it would be of value if those directly interested in spectrography were able to meet at intervals and discuss the various problems which arose in the course of their work. Further, it was considered advisable that representatives of the principal technical institutions and of manufacturers of spectrographic equipment should have the opportunity to attend these discussions. The fundamental policy of the Group required the free interchange of ideas and co-operation in tackling any problems which arose as a result of discussion. Although originally confined to members in the Glasgow area, the success of the Group was such that, in a relatively short time, members representing concerns in Aberdeen, Sheffield, London and other parts of the country were admitted. Meetings of the Group are held in the Royal Technical College, Glasgow, at intervals of approximately six weeks. The chairman is Mr. S. D. Steele, of Babcock and Wilcox, Ltd., Renfrew, Scotland. It has always been considered of first importance that the nature of these discussions be informal, and that in no sense should the Group acquire the character of a society. In this respect it has been found necessary to limit membership to those directly interested in spectrography and also to control membership by invitation. The success of the Group and the progress made have been so marked that it is felt that groups of a similar nature established throughout Britain would be most beneficial.

### Long Ashton Research Station

THE annual report of the Long Ashton Research Station for 1943 has now been published. Several important changes in senior staff appointments mark the period covered, for Prof. B. T. P. Barker, director of the Station during its first forty years, has retired, being succeeded by Prof. T. Wallace, while Mr. A. W. Ling, though still remaining chief agricultural advisory officer in the Bristol Province, has been appointed principal of the Seale Hayne Agricultural College, Devon. The research work undertaken during the year continued to be closely concerned with current problems of the food production programme of the Ministry of Agriculture, and many useful results were obtained, only a few of which can be mentioned here. Tests made with apples, swedes, carrots and potatoes showed that ½–1 per cent naphthalene-acetic acid exerts a delaying action on bud-growth, a fact which should prove of practical importance in preventing sprouting of stored potatoes, while an allied compound, naphthoxyacetic acid, sprayed at the rate of twenty parts per million, had a stimulating effect and increased the yield of Tardive de Leopold strawberries. Outstanding results have

been obtained with dichlor-diphenyl-trichlorethane (D.D.T.) as an insecticide, and the compound seems to merit field trial as a substitute for lead arsenate. Records of mineral-deficiency responses in plants have been extended, and symptoms for twenty-three new crops added to the list. As regards advisory work, a total of 10,880 letters were dispatched and forty-three papers published in scientific journals by members of the Long Ashton, Berkeley Square and Campden staffs.

## Indian Woods for Textile and Jute Mill Accessories

IN *Indian Forest Bulletins* Nos. 121 and 122 (1943) (Forest Research Laboratory, Dehra Dun) substitutes are proposed for imported cotton mill shuttles, bobbins, etc. In Bulletin No. 121, by M. A. Rehman, the results of tests carried out at the Research Institute, Dehra Dun, on the suitability of Indian timbers for cotton mill shuttles for power looms, to replace cornel and persimmon ones imported from America, are described. A large number of timbers considered suitable for their known characteristics were tested. After elimination, the seasoned and selected blanks of woods which appeared promising were sent out for manufacturing trials. The finished shuttles were then tested in weaving mills under factory conditions. Results have shown that the light-coloured sapwood of *Diospyros melanoxylon* or ebony is the best Indian timber so far tested for shuttles. It gives about 50 per cent of the life of imported timber. Other species mentioned in the Bulletin are being used in parts of India where the particular timbers are more easily obtainable.

Bulletin No. 122, by M. A. Rehman and Chheda Lal, treats of the care and seasoning of woods for bobbins, picker arms and jute mill rollers. Suggestions are made for using indigenous woods for the manufacture of these implements; for example, imported bobbins were of beech, birch and maple. Sixteen Indian species of woods belonging to fifteen genera growing in different provinces have been tried out. Species of four of these genera are used extensively throughout the country for bobbin-making. Their life does not appear to be much more than 30 per cent of the imported bobbins. Picker arms and jute mill rollers are also discussed.

## Forests of Trinidad

THE present position of forestry in Trinidad (Trinidad and Tobago, Forest Dept. Admin. Report for Year 1943. Trinidad and Tobago: Govt. Printer) appears to be of considerable interest. There are not many British Colonies which can state that the general position with regard to forest reservation is eminently satisfactory, and that the forest reserves occupy 22·7 of the total area of the Colony "after deducting the area leased to the U.S.A."; and further, that "almost all the forest reserves are now governed by Working Plans under which some form of elementary yield control has been introduced". This is, or should be, the first object in management to be aimed at by the trained forest officer; but, whatever the reasons, it has been neglected in most of the forest regions under the Colonial Office. As elsewhere in the British Empire, the bar-restrictions in timber imports have resulted in the demand for unseasoned local timber exceeding the supply. This being the case, it is difficult to follow the argument that high costs (these prevail everywhere), low volume production per acre (common to the tropical mixed forest generally), and high loss in conversion of tropical woods make it doubtful whether any such supply from the natural mixed forests could in normal times compete with imports. The exploitation of the more or less gregarious *Mora* forests has been under consideration for years; it is now said that there is a high conversion loss owing to the refractory nature of *Mora* as a timber. It would appear that there is now an unexpected chance to introduce, as has always been the case in most parts of India, the indigenous Trinidad timbers to the population in such a manner as to render their use a permanency in the Colony. There is no mention in the report of a recognition of the advantages offered to the type of forests existing in Trinidad by the introduction of a plywood mill.

## British Astronomical Association

A BROCHURE entitled "The British Astronomical Association. Its Nature, Aims and Methods" has been issued by the Association with the main object of encouraging amateurs to undertake astronomical work. Fourteen sections are now in existence, and valuable work is still being done in spite of the difficulties of war conditions. Novices need not be deterred even if they have very little instrumental equipment; in some cases, such as the observation of meteors, auroras, zodiacal light and in historical research, etc., no equipment of any kind is necessary. Proof of the important work that amateurs can do is afforded by a recent triumph of the Computing Section under Mr. J. G. Porter; with the help of four members of this Section, a definitive orbit of Comet Pons-Winnecke has just been computed (*J. Brit. Astro. Assoc.*, 54, 7; 1944). This is probably the first time in the history of astronomy that a body of amateurs has computed a definitive orbit, and it is a testimony to their wonderful patience and skill in handling figures that this formidable work has been accomplished.

Fifty-four years of work by members of the Association have seen much accomplished and also an increasing interest in astronomy. The membership has had a remarkable growth within the last few years and now exceeds 1,200. During the War, the Association moved its meeting place and library to the premises of the Royal Astronomical Society, Burlington House, Piccadilly. Information regarding conditions of membership, etc., should be addressed to the secretary at the above address. Mr. F. J. Hargreaves retired from the presidency in October and the new president is Mr. P. J. Melotte, of the Royal Observatory, Greenwich.

## Public Health in Turkey

THE *Asiatic Review* of October contains an interesting article by Bay Nuzhet Baba on the public health effort and social assistance in Turkey. The central authority in charge of health and social assistance is the Ministry of Health and Social Assistance. Free treatment of the sick, campaigns against epidemics and diseases, especially malaria, trachoma, typhoid fever and dysentery, all fall within the sphere of activity of the Ministry. To the Ministry also are entrusted the supervision of maternity homes, hospitals and sanatoria. In order to emphasize the importance of medical examination of school children, dental care, vaccination against small-pox, inoculations, etc., the Ministry has drawn up regulations whereby municipalities are obliged to provide such

services free of charge. Museums have been established and exhibitions arranged to propagate hygienic principles, and posters and pamphlets are distributed to the villages and displayed in public places.

## Insect Pests of Food

The Ministry of Food has published, under the title of "Insect Pests of Food" (London: H.M. Stationery Office, 5*s*. net), two important papers on moths and their larvæ affecting stored products. They are designed to provide a reliable and up-to-date guide to the identification of the insects referred to. Although the two papers are primarily for the use of the Ministry's inspectors, they will be valuable to anyone concerned with the pests in question. The paper on lepidopterous larvæ affecting stored products is by Dr. H. E. Hinton and was originally published in the *Bulletin of Entomological Research* (**34**), and that on the moths by Dr. A. S. Corbett and Mr. W. H. T. Tams is reprinted from the *Proceedings of the Zoological Society of London* (**113 B**).

## Domestic Electrical Accessories

The design and installation of electrical accessories for domestic purposes was dealt with in a paper read by F. C. Fuke in London recently before the Institution of Electrical Engineers. The paper states the requirements which the design of electrical accessories must fulfil and how such requirements can be met. Contacts and switching are dealt with at some length, because of their effect upon the performance and life of most accessories. The fundamentals of fuse design are given, as well as the reason for possible indiscriminate operation between fuses of different types. The need to break away from some time-honoured practices is shown, with particular reference to plugs and tumbler switches, and solutions based on theoretical and practical considerations are presented. The author considers that British Standard Specifications should be confined to setting standards of performance, with interchangeability only where required, and that constructional details and dimensions should be omitted so as to give maximum freedom for development and, therefore, progress in design.

## Botanical Periodicals at Oxford

A catalogue of interest and value to all research workers and teachers in botany who wish to consult out-of-the-way journals as well as those more easily obtained has just appeared in the "List of Periodicals" issued by the Library of the Botany Department at Oxford. The purpose of the Library is, of course, to serve in the first place the needs of the Department, and this list was naturally prepared to that end; it is, however, now available for limited circulation. It is obvious that the privilege of borrowing books for use outside Oxford can only be granted in exceptional cases and through recognized channels; but the list will undoubtedly be of assistance to those in need of periodicals otherwise obtainable only with great difficulty and to whom these channels are available. The list is clearly annotated, the information being obtained chiefly from the periodicals themselves, and a useful feature is that all journals with current numbers in the Library are printed in bold type.

## Recent Earthquakes

The United States Coast and Geodetic Survey, in co-operation with Science Service and the Jesuit Seismological Association, has determined the provisional epicentres of five recent earthquakes. The first, on August 7, at 3h. 25·3m. G.M.T., had its epicentre at 16·9° S., 71·5° W., which is in Peru. The second, on August 10, at 1h. 52·7m. G.M.T., had its epicentre at 51·4° N., 130·5° W., which is south of Queen Charlotte Islands, off British Columbia. The third, on August 18, at 10h. 33·1m. G.M.T., had its epicentre at 35° N., 137° E., which is in Japan. The depth of focus of this shock was probably near 200 km. The fourth shock occurred on August 24 at 23h. 37·8m. G.M.T., and had its epicentre at 15° N., 93° W., which is in Guatemala. The depth of focus of this shock was slightly less than 100 km. The fifth earthquake occurred on September 5 at 4h. 38·8m. G.M.T. It had its epicentre at 45° 01′ N., 74° 44′ W.

On October 6, at about 5.30 a.m. local time, an earthquake in Anatolia, south of the Dardanelles and near the ruins of Troy, is reported to have destroyed 4,000 buildings in Ayvalik, Edremit, and the surrounding district, and to have caused the deaths of 44 persons; 112 others are reported injured as a result of the earthquake. Further news of this shock is awaited.

## Announcements

Sir Fred Clarke, director of the Institute of Education and professor of education in the University of London, will retire under the age limit on September 30, 1945, and the University has appointed Prof. G. B. Jeffery, Astor professor of mathematics at University College since 1924, to succeed him in the post of director of the Institute.

Brigadier George Macdonald, assistant director since 1939 of the Ross Institute of Tropical Hygiene, London School of Hygiene and Tropical Medicine, has been appointed director of the Institute and will take up his appointment on release from the Services.

Dr. A. G. Sanders has been appointed medical adviser in China to the British Council and has arrived in Chungking. Dr. Sanders is one of the group of Oxford workers, led by Sir Howard Florey, who developed and extended Sir Alexander Fleming's earlier work on penicillin. He was chiefly responsible for the design and construction of the apparatus used for large-scale laboratory production of penicillin. The primary object of his visit is to investigate and organize the exchange of information between China and Britain on matters of importance in medical science and practice; and he will be working under the direction of Dr. Joseph Needham, director of the British Council Cultural Scientific Office at Chungking.

Sir John Russell, who has for the past eleven weeks been in a nursing home where he has undergone a surgical operation, is sufficiently recovered to be able to return shortly to his home at Campsfield Wood, Woodstock, Oxfordshire.

The following appointments have recently been made by the Colonial Office: R. A. Butt, to be assistant conservator of forests, Uganda; J. D. Farquhar, to be assistant conservator of forests, Palestine; G. Watkins, to be assistant conservator of forests, Tanganyika; R. D. Hodgins, to be veterinary officer, Northern Rhodesia; R. P. Lee, to be veterinary officer, Tanganyika; H. S. Darling, plant protection officer, Palestine, to be entomologist, Uganda.

# LETTERS TO THE EDITORS

*The Editors do not hold themselves responsible for opinions expressed by their correspondents. No notice is taken of anonymous communications.*

## Generic and Specific Trivial Names of the Tertian and Quartan Malaria Parasites

THE "Official List of Generic Names in Zoology" was established by the International Congress of Zoology in order to promote stability in zoological nomenclature by placing on record the correct names of the principal genera in each of the classes and orders of the animal kingdom, together with their type species. Hitherto names have been placed on the "Official List" in *Opinions* rendered by the International Commission on Zoological Nomenclature, but in 1943, the International Commission decided that it was desirable to make the "Official List" more readily available, and accordingly decided to publish it as soon as possible in convenient book form and with a full index. The preparation of the "Official List" for publication in this way, which was begun in the autumn of 1943, involved the checking of all the relevant bibliographical and other references to the generic names concerned and their type species. In the course of this work, errors were detected in a number of the *Opinions* containing decisions relating to the "Official List". These errors are being brought at once to the attention of the International Commission with the view of its rendering an *Opinion* as soon as possible containing such rectifications as may be necessary.

Among the errors detected were errors in the entries in *Opinion* 104 (published in 1928) relating to the author's name and date of publication of the generic name for the malignant tertian malaria parasite (*Laverania* Feletti and Grassi, 1889). Further, in the case both of this name and of that for the quartan parasite (*Plasmodium* Marchiafava and Celli, 1885) the type species was found to have been cited under a name which was not the correct name under the International Code of Zoological Nomenclature.

The names of these parasites, as recorded in *Opinion* 104, are the names now universally employed for these species in the enormous medical and technical literature relating to malaria, and it would clearly be as wrong as it would be impracticable to attempt to introduce changes in such names merely on grounds of zoological nomenclature. In the present case such changes would be particularly undesirable, since they would involve the transfer of the specific trivial name *malariæ* from the quartan parasite (on which it was bestowed by Grassi and Feletti, 1890), by which name this species is universally known, to the malignant tertian parasite on which, in 1881, it had been independently bestowed by Laveran (and by which name this species is never called). Transfer of trivial names in this way causes great confusion, and the only solution in such a case is for the International Commission to use its plenary powers to suspend the rules in order to validate the names currently in use.

It was accordingly decided early in 1944 to invite the International Commission to deal with this question under its plenary powers, and, for this purpose, a thorough investigation into the highly complicated literature of these names was made, with the assistance of Sir Rickard Christophers and Brigadier J. Sinton, whose paper, "The Correct Name of the Malignant Tertian Malaria Parasite", published in 1938 (*Brit. Med. J.*, ii, 1130; 1938), must form the starting point of any work on this subject. In the course of this investigation, names previously overlooked were brought to light and other unsuspected nomenclatorial difficulties were disclosed. A paper setting out in detail the present position under the International Code and containing recommendations to the Commission for placing the whole matter on a satisfactory footing has been prepared and will appear in the next part of the *Bulletin of Zoological Nomenclature*, the official organ of the International Commission on Zoological Nomenclature.

Quite recently, the officer in charge of malaria control in war areas, Atlanta, Georgia, U.S.A., communicated to the International Commission an application prepared by Drs. Curtis W. Sabrosky and Robert L. Usinger, U.S. Public Health Service, directing attention to the errors in *Opinion* 104 and requesting the International Commission to use its plenary powers to suspend the rules for the purpose of validating existing nomenclatorial practice in regard to these parasites. This application has since been published in *Science* of September 1, 1944. It is extremely gratifying to the Executive Committee of the International Committee to find that malariologists in the United States, working independently, have reached substantially identical conclusions in regard to this matter, since this should greatly facilitate the early adoption by the International Commission of an *Opinion* setting this matter at rest once and for all.

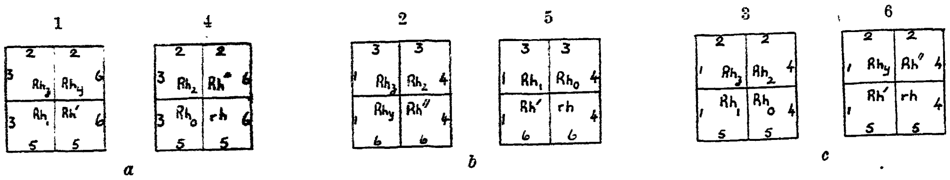
In order to secure the widest support for the action proposed to be taken, the Executive Committee, on behalf of the International Commission, invites expressions of opinion from specialists concerned in any aspect of the malaria problem. Such communications, which should be addressed to the International Commission on Zoological Nomenclature at its Publications Office, at 41 Queen's Gate, London, S.W.7, will at once be published in the Commission's official organ, the *Bulletin of Zoological Nomenclature*, in order that the whole of the material relating to this case may be before the commissioners when reaching their decision.

FRANCIS HEMMING.
Secretary,
International Commission on
Zoological Nomenclature.

## A Nomenclature of Subgroups of the *Rh* Factor

SINCE Race added two further hypothetical allelomorphs tentatively called $Rh_y$ and $Rh_z$ to the six genes recognized by Wiener[1], which had been independently discovered by Taylor and Race (namely, $Rh_1$, $Rh_2$, $Rh_0$, $Rh'$, $Rh''$ and $rh$), the terminology is somewhat confused. Recently Race[2] has described Prof. R. A. Fisher's ingenious system of three allelomorphic antigens named *Cc*, *Dd*, *Ee*, with Greek lettering for the antisera. They predict the existence of two as yet undiscovered antisera $\eta$ and $\delta$. The disadvantage of this scheme is the duplicate system of lettering.

The nomenclature now suggested is simple; it is based on the numbering of the antisera 1 to 4[3], and could easily be extended. It is proposed that the reaction of cells should be expressed in terms of the



*a* *b* *c*

sera with which they react. Its value lies chiefly in the naming of phenotypes, so that at a glance it may be seen exactly with what sera the cells have been tested. Eight genes have now been postulated, and their reactions with the four sera so far discovered can be set out as follows:

| Red cell genes | Antisera 1 | 2 | 3 | 4 |
|---|---|---|---|---|
| | Anti $Rh_1$ | Anti $Rh_2$ | Standard | *St* |
| $Rh'$ | + | — | — | — |
| $Rhy$ | + | + | — | — |
| $Rhz$ | + | + | + | — |
| $Rh_1$ | + | — | + | — |
| $Rh''$ | — | + | — | + |
| $Rh_2$ | — | + | + | + |
| $Rh_0$ | — | — | + | + |
| $rh$ | — | — | — | + |

It will be seen that the table is completely symmetrical, and that cells which react with serum 1 fail to react with serum 4 and *vice versa*. Thus the reactions of the eight genes can be arranged as in the accompanying diagrams at (*a*).

The two undiscovered antisera of Fisher we will call 5 and 6. Thus the reactions of serum 5 and serum 6 will be related to those of serum 2 and serum 3, in the same way as serum 4 is to serum 1, and are shown as (*b*) and (*c*) in the diagrams.

From these diagrams can be seen the possible antisera which may arise by stimulation with any one of the eight genes. For example, $Rh_z$ will react with sera 1, 2 and 3 and will therefore be designated $Rh_{123}$; again, $Rh_1$ will react with sera 1, 3 and 5 and will therefore be called $Rh_{135}$. Thus the conclusion by Stratton[4] that $Rh_0$ can stimulate the production of sera 1, 2 and 3 would appear to be incorrect—$Rh_0$ can produce or react only with sera 3, 4 or 5.

A complete comparison of names of sera and genes with their corresponding reactions, including those of the two undiscovered sera, is given in the accompanying table. My numbering of sera and genes is compared with the original names and Prof. Fisher's recent notation described by Race[2].

REACTIONS OF EIGHT GENES TO SIX POSSIBLE ANTISERA (FOUR OF WHICH ONLY HAVE BEEN FOUND).

| | | | Antisera | | | | | |
|---|---|---|---|---|---|---|---|---|
| Wiener *et al.* Race and Taylor | | | Anti $Rh_1$ | Anti $Rh_2$ | Standard | *St* ? *Hr* | As yet undiscovered | |
| Fisher's notation | | | Γ | H | Δ | γ | η | δ |
| Suggested numbering | | | 1 | 2 | 3 | 4 | 5 | 6 |
| Red cell genes | | | | | | | | |
| $Rh'$ | *Cde* | $Rh_{156}$ | + | — | — | — | + | + |
| $Rhy$ | *CDe* | $Rh_{126}$ | + | + | — | — | — | + |
| $Rhz$ | *CDE* | $Rh_{123}$ | + | + | + | — | — | — |
| $Rh_1$ | *CdE* | $Rh_{135}$ | + | — | + | — | + | — |
| $Rh''$ | *cDe* | $Rh_{216}$ | — | + | — | + | — | + |
| $Rh_2$ | *cDE* | $Rh_{234}$ | — | + | + | + | — | — |
| $Rh_0$ | *cdE* | $Rh_{345}$ | — | — | + | + | + | — |
| $rh$ | *cde* | $Rh_{456}$ | — | — | — | + | + | + |

Selected from my series of families with fœtal hæmolytic disease, four illustrative cases show the mechanism of immunization of the mother, who can only become sensitized to an antigen of her husband which she herself does not possess.

There appears to be some variation in the response of individuals to similar antigenic stimulation. Thus an *Rh* negative mother ($Rh_{456}$) with a homozygous $Rh_1$ husband ($Rh_{135}$) usually produces a mixture of two antisera 1 and 3, giving together 87 per cent positive reactions (Wiener's anti-$Rh'$):

| | Father | Mother | Antiserum produced |
|---|---|---|---|
| Case 1 | $Rh_1Rh_1$ | *rhrh* | |
| Mrs. Ba. | 135 | 456 | Nos. 1 and 3 |

But in some identical matings the antiserum 1 giving 70 per cent reactions (Wiener's anti-$Rh_1$) may be produced:

| | Father | Mother | Antiserum produced |
|---|---|---|---|
| Case 2 | $Rh_1Rh_1$ | *rhrh* | |
| Mrs. Br. | 135 | 456 | No. 1 |

In these cases we must suppose that some antiserum 3 (Wiener's standard) is called forth, but only in such weak titre that it is not detectable under the conditions of the test, since we do find that the sera 1 and 3 may be in varying proportions so that it is sometimes possible to dilute out the antiserum 3 from the mixture retaining antiserum 1 in a strong workable titre. In the same way the figures 1 and 3 may be present in the genotype of the stimulating fœtal cells and yet an apparently pure antiserum 3 (Wiener's standard) may appear in the maternal serum:

| | Father | Mother | Antiserum produced |
|---|---|---|---|
| Case 3 | $Rh_1Rh_z$ | *rhrh* | |
| Mrs. R. | 135 123 | 456 | No. 3 |

Similarly, the two components of mixtures of antisera 2 and 3 giving 87·0 per cent positive reactions (Wiener's anti-$Rh''$) may vary, and we can only expect a pure antiserum 1 or antiserum 2 in cases where it is not possible for antiserum 3 to be stimulated, that is, where the figure 3 occurs in the genetic formulæ of both husband and wife:

| | Father | Mother | Antiserum produced |
|---|---|---|---|
| Case 4 | $Rh_2Rh_2$ | $Rh_1Rh_1$ | |
| Mrs. M. | 234 | 135 | No. 2 |

As yet, antisera 5 and 6 have not been demonstrated, although cases with a suitable genetic arrangement have been encountered. It may be just chance that no antibodies have been stimulated, or it may be that factors 5 and 6 are only weakly antigenic and do not readily provide the stimulus.

## Gramicidin S and its use in the Treatment of Infected Wounds

ANTISEPTICS of biological origin are now well known since the pioneer investigations of Fleming on penicillin and Dubos on tyrothricin. In our laboratory early in 1942 an attempt was made to isolate the strains of *Bacillus brevis* from Russian soils in order to prepare tyrothricin similar to that of Dubos. In the course of this work we isolated from soil a new strain of aerobic sporulating bacillus possessing some unique characteristics. It is well known that alcoholic extract of the acid precipitate of the culture of *B. brevis* contains an amorphous body, designated by Dubos and Hotchkiss (1941) as tyrothricin, which can be afterwards fractionated by special procedures into two individual crystalline substances, gramicidin and tyrocidine hydrochloride. In distinction from this, alcoholic extract of the acid precipitate from our strain consists almost entirely of the antibacterial substance, which is not amorphous but is directly crystallizable from the alcoholic solution. This crystalline substance can be further purified and obtained in the form of colourless needles with the melting point 267–268°. Hence it is different from gramicidin (m.p. 228–230°) and tyrocidine hydrochloride (m.p. about 240°). The bacteria producing this substance were designated as the strain of Gause-Brazhnikova, and the substance itself as gramicidin *S* (Soviet gramicidin).

*Chemical properties and antagonistic effect of gramicidin S.* Gramicidin *S* differs from tyrothricin, gramicidin of Dubos and tyrocidine hydrochloride by its easy solubility in chloroform. We had an opportunity of comparing directly gramicidin *S* with the original preparation of tyrothricin, obtained from Lederle, Inc., New York. Further, we were able to compare the properties of our strain of bacillus with that used by Lederle for the commercial production of tyrothricin. It was occasionally discovered that a batch of tyrothricin obtained from Lederle is heavily contaminated with spores of some bacillus. This bacillus was found to be identical with that described by Dubos, and with its aid we prepared a batch of tyrothricin identical with that offered by Lederle. It was observed by us that the spores of the Dubos strain of bacteria are much more resistant to the action of ethyl alcohol than the spores of the strain of Gause-Brazhnikova.

Although gramicidin *S* is similar to tyrothricin in many respects, a direct comparison shows that it is about four times more efficient in killing staphylococci than tyrothricin. Numerous tests made with various strains of pyogenic cocci on the nutritive media containing 10 per cent of human blood serum have shown that 25 gamma of gramicidin *S* per 1 c.c. of the medium is sufficient to kill staphylococci, whereas 100 gamma of tyrothricin is required for the same effect. These experiments were made with the commercial preparation of gramicidin *S*, which is now available in bulk. (Staphylococci are killed by pure crystalline gramicidin *S* at a concentration of 3 gamma, and *B. coli* at 50 gamma per 1 c.c. of the nutritive medium.) In the case of streptococci and pneumococci, 6 and 12 gamma of gramicidin *S* respectively are sufficient for the killing action, whereas about 3 gamma of tyrothricin has the same effect. It follows from these data that gramicidin *S* is more regular in its action upon various genera of pyogenic cocci, whereas tyrothricin has a weak action upon staphylococci and a strong effect upon streptococci and pneumococci. Because septic wounds containing staphylococci cause the most trouble, the advantage of gramicidin *S* for surgical practice is obvious.

The action of gramicidin *S* upon gas bacilli was studied by a number of methods. It was found that 10 gamma of this substance per 1 c.c. of the medium is sufficient to kill *Cl. Welchii* and *Cl. histolyticus.*

The toxicity of gramicidin *S* equals that of tyrothricine: the median toxic dose for intraperitoneal injections in rats is 15–20 mgm. per kgm. weight.

The use of gramicidin *S* in the prophylactic treatment of experimental infections was also studied. Experimental lacerated wounds of muscles in guinea pigs were infected with *Cl. Welchii*, treated either by gramicidin *S* solution (experiment) or by physiological saline (controls), and repaired. The mortality in experimental animals was 5 per cent, whereas in controls it attained 53 per cent. Similar experiments were made on rats, where the experimental wounds were infected by garden soil. The mortality of controls was 100 per cent, whereas in the rats treated by gramicidin *S* it was only 40 per cent.

*Clinical results.* Clinical application of gramicidin *S* was studied in 573 cases. The original 4 per cent alcoholic solution of gramicidin was diluted by water to make the concentration of gramicidin 400–800 gamma per c.c. of the liquid. These solutions were applied daily either locally, or introduced into cavities. The results of clinical observations can be summarized as follows.

The first group of cases includes septic gunshot wounds of the hip; the suppuration following heavy burns of the abdomen, breast, hip and hands; abscesses of the abdominal wall; heavy anaerobic phlegmones, etc. The application of gramicidin *S* has led to: (1) rapid disappearance of bacteria in the wound and successful epithelization; these processes were controlled by cytological and bacteriological observations; (2) successful preparation of the wound for subsequent surgical treatment (secondary joint or the transplantation of the skin); (3) in some cases the septic state disappeared through the elimination of the local suppuration process.

The second group of cases includes septic gunshot wounds of the larynx, chronical otitis, etc. The application of gramicidin *S* dramatically arrests the suppuration and rapidly improves the general state of the patient.

The third group of cases consists of empyæmas. Removing the pus by a syringe and introducing 50–100 c.c. of a water solution of gramicidin *S* into the pleural cavity two or three times is usually sufficient to eliminate the infectious process entirely.

The fourth group of cases includes osteomyelitis. The heavy suppurations of gunshot fractures are rapidly arrested by the local application of gramicidin *S*. In the cases of chronical osteomyelitis the application of gramicidin *S* immediately after the performance of sequestrectomy arrests the further spread of suppuration.

Details of experimental and clinical work with gramicidin *S* have been published in a monograph entitled "Soviet Gramicidin and Wound Healing", which is issued in Moscow in Russian. Copies of this monograph are available, and can be sent on application.

## Symmetrical and Asymmetrical Post-reduction in Ascomycetes

The analysis of asci has shown that a pair of allelomorphic genes may segregate at the first meiotic division (pre-reduction) or at the second (post-reduction). Post-reduction may be symmetrical, with two like genes adjacent in the middle of the ascus, or asymmetrical. The analysis of 77 asci of *Neurospora sitophila* by Whitehouse[1], and 31 by Wilcox[2], Dodge[3] and Lindegren[4] has given the six possible patterns of the sex genes in the following numbers:

| | | | | | |
|---|---|---|---|---|---|
| Pre-reduction | + | + | − | − | 26 |
| | − | − | + | + | 24 |
| Symmetrical post-reduction | + | − | − | + | 10 |
| | − | + | + | − | 11 |
| Asymmetrical ,, ,, | + | − | + | − | 18 |
| | − | + | − | + | 19 |

The distal end of the ascus is represented to the left. There were thus 37 asymmetrical and 21 symmetrical post-reductions. The probability of so great a divergence from equality by chance is 0·049. If we add to these the figures obtained by Whitehouse for the segregation of 'weak', which is at least 41 units from 'sex' in the same chromosome, and of 'orange', which is in a different chromosome, based on 31 asci, and Dodge's data for albinism, which is also in a different chromosome based on 7 asci, we find 49 asymmetrical and 27 symmetrical reductions. The probability of obtaining such unequal numbers by chance is 0·016. On the other hand, Lindegren's data on 273 asci of *Neurospora crassa* show 14 asymmetrical and 25 symmetrical post-reductions. The difference is not significant; but it is unlikely that a larger count would show a majority of asymmetrical post-reductions. So asymmetrical post-reduction seems to be more frequent, at least for some genes, in *N. sitophila*, but not in *N. crassa*. Zickler's[5] results on *Bombardia lunata* show a slight but significant excess of asymmetrical post-reductions for the characters *lactea* and *rubiginosa*.

The greater frequency of asymmetrical post-reduction can be explained if the relative position of the chromatids generally remains unaltered during interphase.

Full details will be published elsewhere.

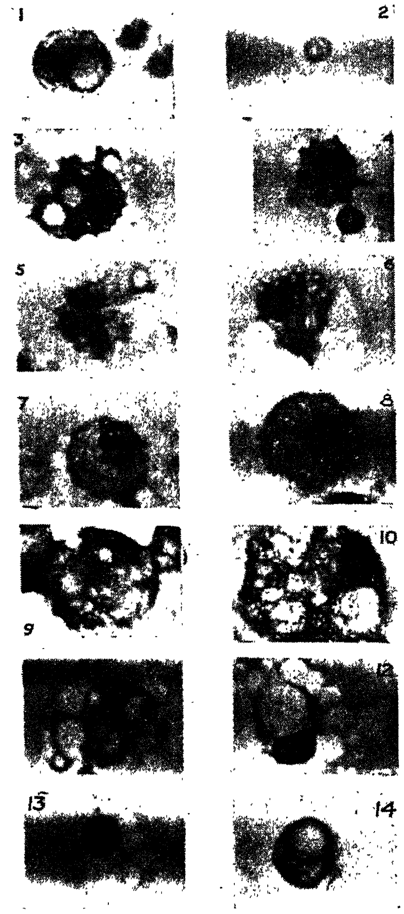
## Cell Contents of Milk

Being interested in the study of the cell contents of milk, I have investigated the colostrum bodies present in fresh human and cow's milk. I devised two methods of studying the milk cells: in wet films, staining the nuclei with methylene blue; and by dry films, staining with May Grunwald Giemsa. The smears were made from fresh milk, at the commencement of lactation, and some smears were made from the cells deposited after centrifuging.

In the wet films, I found different groups of cells. (1) The first group were cells with polymorph nuclei, which appeared to be just a little larger than the normal polymorph, and their cytoplasm seemed to be formed by small fat droplets. (2) The second group were mononuclears containing a similar number of fat droplets to the previous group of cells, the droplets varying in size from those contained in the polymorphs to drops of more or less the size of red blood corpuscles. A few of the mononuclears in this group were two or three times the diameter of a polymorph. Their appearance was similar to the cells observed in the fluid obtained from some hæmorrhagic cysts in thyroid glands (described elsewhere). (3) The third group was composed of mononuclears containing a smaller number of fat droplets. Some of the smaller cells contained only one drop of fat and a small quantity of cytoplasm, giving the cell the aspect of a lymphocyte attached to a fat droplet.



*Wet Films.* Nos. 1 and 2. A mononuclear full of fat droplets; and a lymphocyte containing one drop of fat.
*Dry Films* (stained with May Grunwald Giemsa). Nos. 3, 4, 5, 6. Different polymorphs with different sizes of fat droplets.
Nos. 7, 8, 9, 10. Mononuclears in full process of secretion of fat droplets.
Nos. 11, 12, 13. Cellular remnants of fat secretion. In Nos. 12 and 13 the remnants appear as lymphocytes.
No. 14. Protoplasmatic remnants framing some fat droplets.

In the dry films, the cells could also be divided into groups and confirmed what we had previously seen in the wet films. By careful observation, however, it could be seen that the cells were not in three distinctly different groups, but were linked together by intermediate cells. The groups observed in the dry films were as follow: (1) The first group was formed by polymorphs which appeared to be of the neutrophil variety, part of their cytoplasm consisting

mainly of empty vacuoles. The material contained in these vacuoles had probably been dissolved in the alcohol used as a solvent for the stain. These polymorph cells had different aspects, and the vacuoles contained in them were of different sizes. In some of the cells the nucleus was compressed by the large size of the fat droplets, and in the cells generally the change in the nuclei towards a mononuclear could be followed clearly. (2) The second group consisted of a range of mononuclear cells of different sizes, each having a large quantity of cytoplasm containing vacuoles. Some of the cells were of very large size, and some of the vacuoles contained in these large cells had a diameter about the size of a red blood corpuscle. (3) The third group consisted of cells still containing vacuoles; but the cells were closer to the classical description of a peripheral blood monocyte. It could be observed that some of these cells in evolution were linked with the lymphocyte, and some of the lymphocytes present still contained vacuoles in their cytoplasm.

Another fact which could be seen clearly was that some cells liberate portions of their cytoplasm, each such portion taking on the form of a round drop. Some of these free cytoplasmic portions still framed empty vacuoles.

After systematic observation of different specimens of human and cow milk in which I had followed the monoglandular fat secretions, I was able to draw similar conclusions to those arrived at after my study of blood formation, previously published elsewhere.

My grateful thanks are due to my technician, Mr. Jeffrey B. Dean, who has made the photomicrographs.

*Conclusions.* (1) It appears that a number of fat droplets, if not all, are not produced by the mammary gland itself but are carried there by cells. (2) The cells responsible for the carriage of the fat are a kind of polymorph neutrophil. (3) The cell that secretes the fat droplets is the same polymorph neutrophil that carries the fat to the gland, but it changes its nuclear morphology and its size before it undertakes the process of secretion. (4) After secreting and expelling its cytoplasmic fat droplets, the cell has the appearance of a lymphocyte.

## Determination of Molecular Weights by the Cryoscopic Method

THE difficulty of obtaining consistent results in the determination of molecular weights by the cryoscopic method has led Brancker, Leach and Daniels[1] to suggest a modified form of the classical cryoscopic equation. The difficulty arises from the fact that as the concentration of the unknown solute is changed, the molecular weight, as calculated by the classical equation, does not remain constant. In order to overcome this difficulty, these workers used the equation

$$\Delta T = K_f m^b.$$

In this laboratory we have confirmed that unless special methods of calculation are used, inconsistent results are invariably obtained, the inconsistency becoming more marked as the molecular weight of the unknown increases. It has been found, however, that results can be duplicated within narrow limits by the use of the above modified equation. Table 1 shows the results obtained on a series of oils. Duplicate figures on each material were obtained with different samples of solvent (benzene). The cryoscopic constant was determined on each sample using naphthalene as solute, and five depressions of freezing point were determined on each material, including standardizations with naphthalene.

TABLE 1.

| Oil | $b$ | $\log K_f$ | $M$ | ($M$ Theoretical) |
|---|---|---|---|---|
| Dibutyl phthalate | 1·0173<br>0·9990 | 0·6885<br>0·6953 | 256·1<br>259·4 | 278 |
| Tricresyl phosphate | 0·9927<br>0·9751 | 0·6890<br>0·6921 | 349·1<br>335·1 | 368 |
| "Octoil S" | 1·0968<br>1·0789 | 0·6885<br>0·6890 | 340·2<br>341·5 | 426 |
| "Octoil" | 1·0314<br>1·0186 | 0·6885<br>0·6890 | 352·5<br>352·0 | 390 |
| "Litton" oil | 0·9597<br>0·9723<br>0·9350 | 0·6953<br>0·6953<br>0·6885 | 486·1<br>491·0<br>487·6 | — |
| Pump lubricating oil | 1·0162<br>0·9925 | 0·6953<br>0·6890 | 301·1<br>311·8 | — |
| "Arochlor 1254" | 1·0129<br>1·0228 | 0·6921<br>0·6953 | 327·9<br>315·8 | — |
| "Apiezon A" oil | 0·9468<br>0·9584 | 0·6890<br>0·6885 | 445·1<br>448·7 | — |
| "Apiezon B" oil | 0·9613<br>0·9495 | 0·6953<br>0·6885 | 523·7<br>515·9 | — |

It will be seen that the results are very consistent. It is also interesting to note that values of $b$ in excess of unity may be obtained. The cause of this has not been determined. Dibutyl phthalate, tricresyl phosphate, 'Octoil' (di-octyl phthalate) and 'Octoil S' (di-octyl sebacate) were obtained commercially, and as they were to be compared with other materials, no attempt was made to purify them. A comparison of their theoretical and determined molecular weights has been made in Table 1. While the discrepancy between these figures is fairly large, it must be remembered that the materials were not pure, and in addition the determined figures on each sample are in very good agreement. The modified equation is admittedly empirical and must be judged as such until other methods of checking molecular weight determinations have been carried out.

Brancker, Leach and Daniels have compared the results obtained with the classical equation with those obtained with the modified equation. In their table of results, they have calculated $K_f$ according to the latter equation and substituted in the classical. Another method of calculation would be to calculate $K_f$ and the unknown molecular weight at the same concentration of solute in both cases, using the classical equation.

Neither of these methods is permissible. The latter is only applicable when the molecular weight of the unknown is of the same order as the standardizing solute (namely, 128 in the case of naphthalene).

It must be borne in mind that the use of osmotic or cryoscopic methods for determination of molecular weight lead to a 'number average', and hence comparable values are only obtained when equal molalities of solution are used in both $K_f$ and unknown molecular weight determinations. For example, the concentration of an unknown compound

of molecular weight 400–500 should be four times as high when its depression is found as the naphthalene concentration when $K_f$ is determined.

This method of calculation has been used for 'Litton' oil (Table 2), and it will be seen that the average result obtained is comparable with that obtained by the modified equation. The figures in the second column of this table are those obtained from the classical equation using the cryoscopic constant calculated from the modified equation.

TABLE 2. COMPARISON OF RESULTS OBTAINED USING MODIFIED AND CLASSICAL EQUATIONS.

("Litton" oil).

| Modified equation | | Classical equation | | "Number average" (see text) | |
|---|---|---|---|---|---|
| 495·1 | 491·0 | 451·2 | 460·0 | 476·8 | 481·4 |
| 489·8 | | 455·9 | | 478·7 | |
| 481·7 | | 452·9 | | 474·2 | |
| 488·9 | | 463·3 | | 483·1 | |
| 499·4 | | 476·6 | | 494·2 | |

From the figures obtained in this Laboratory, there seems to be little doubt as to the greater consistency of results using the modified equation over those obtained by the classical method of calculation. For purposes of laboratory control of products, this is essential.

A comparison of results obtained by osmotic and cryoscopic methods of determination of molecular weight would be interesting and may prove of considerable importance in the determination of molecular weights of high polymers.

I wish to thank Dr. A. P. M. Fleming, director of research and education, Metropolitan-Vickers Electrical Co., Ltd., for permission to publish these notes.

## Formation of Sulphamic Acid during the Thermal Decomposition of Ammonium Sulphate

THE thermal decomposition of ammonium sulphate appears to have received little attention since the recorded observations of Jänecke in 1921[1]. Consequently it has become accepted that decomposition results first in the formation of ammonium acid sulphate with the liberation of ammonia, and then, after partial elimination of water from the acid sulphate, the pyrosulphate is formed.

Recent observations in this laboratory have revealed that sulphamic acid is also formed during the thermal decomposition of either the normal or the acid sulphate. Analyses of residues obtained from heating A.R. ammonium sulphate at 400° C. indicated that they consisted predominantly (90 per cent) of ammonium pyrosulphate, together with small amounts of the acid salt and unchanged ammonium sulphate. However, it was found that when the residues were treated with water and redried at 150° C., the resulting increase in weight was greater than could be accounted for by hydrolysis of pyrosulphate to the acid salt. This indicated that one of the components of the mixture contained even less water than ammonium pyrosulphate, and the presence of sulphamic acid was thus suspected.

Quantitative measurements of sulphamic acid by the gas volumetric method of Meuwsen and Merkel[2] have shown that about 5 per cent of sulphamic acid is present after 1 hour at 400° C. The results given in the accompanying table are representative of the composition of the residues obtained.

The evolution of sulphur dioxide and nitrogen from strongly heated ammonium sulphate, which has previously been ascribed to the decomposition of the acid salt[3], is probably due to the thermal decomposition of sulphamic acid which is first formed.

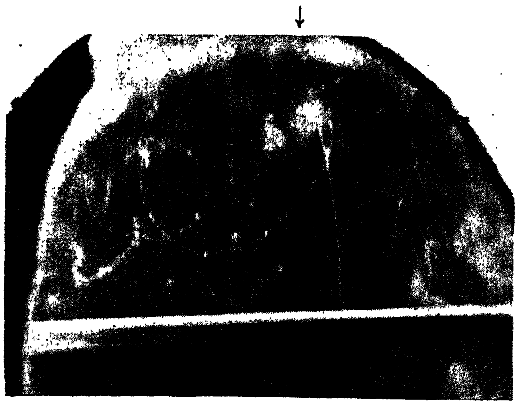
## Application of a Randomly Operated Large Wilson Cloud Chamber for the Determination of the Mass of the Meson

DURING recent years, increasing interest has been shown in the accurate determination of the mass of mesons, which have been supposed to constitute the penetrating component of cosmic rays. The most direct evidence that such particles have an intermediate mass lying between that of an electron and a proton comes from cloud chamber observations. The momenta of the particles and ionization they produce are directly available from the measurements on the cloud chamber tracks, and are found to be compatible with theory only when the particles are assumed to possess a mass roughly equal to 200 times the mass of an electron. An accurate determination of the mass is possible only when the particle can be photographed near the end of its path through space, and this occurs rarely. Slow mesons seem to be particularly rare in counter-controlled photographs with a thick lead plate inserted inside the chamber, apparently because (1) they have extremely short range in heavy material, (2) they have a large probability of decay, nuclear absorption and transformation into neutrettos[1]. Hence they fail to trip the lower counter of the coincidence system.

A large randomly operated cloud chamber has been found[2,3] to be very satisfactory for such investigations, and with the view of determining the mass of mesons, their decay products and the absorption processes, such a cloud chamber has been built. Progress has been very slow, and due to shortage of films only three hundred photographs could be taken altogether, of which the accompanying photo-

| $(NH_4)_2SO_4$ (gm.) | Temperature °C. | Time of heating (hr.) | Residue (gm.) | Composition of residue (per cent). | | | |
|---|---|---|---|---|---|---|---|
| | | | | $(NH_4)_2SO_4$ | $NH_4HSO_4$ | $(NH_4)_2S_2O_7$ | $NH_2SO_3H$ |
| 5·0000 | 400 | 1·0 | 3·5499 | 10·3 | 13·5 | 70·2 | 5·7 |
| 5·0000 | 400 | 1·25 | 3·4817 | 9·9 | 11·2 | 73·2 | 5·7 |



graph is one. The interesting feature of the track marked by an arrow is that it ends just a centimetre above the lead plate. The absence of any decay product in the neighbourhood indicates the absorption of a meson by a nucleus present in the gaseous volume of the chamber. The charge carried by the particle is negative. It is interesting to note that decay products are obtained only in the case of positive mesons, while negative mesons show absorption. Rassetti[4] has pointed out that this may be because slow positive mesons are repelled by the positively charged nuclei. The other suggestion given by Hamilton, Heitler *et al.*[1] is that when a meson has reached an energy which is lower than four times its rest energy, the chance that it will be transformed into a neutretto on interacting with a nuclear particle is so large that only 21 per cent of them can reach the end of their range as charged mesons.

The ionization density along the photographed track is too heavy to allow direct counting under the microscope. Another method that has been experimentally verified and used by Williams and is particularly suitable for large ionization density is the counting and measurement of the long free paths of the particle observed along the track which appear as gaps. The average number of such free paths, greater than $g$ cm., is given by the well-known formula of random collisions, $n = Il \times e^{-Ig}$, where $I$ is the ionization density and therefore the inverse of the mean free path, and $l$ is the length of the track. In this case only one free path was measured on 5·2 cm. of track and was found to be 0·056 cm., being corrected for the width of the track. Hence $5{\cdot}2\,I \times e^{-0{\cdot}056\,I} = 1$ and $I = 113$ ions/cm., which after correction for temperature and pressure gives $I = 106$ ions per cm. at N.T.P.

The track was photographed in a magnetic field of 1,060 oersteds. The curvature was measured by finding the value of the dips at different points along the track. The radius of curvature was found to be 76 cm. Hence $H\rho = 8{\cdot}056 \times 10^4$ gm. cm.

Now $pc = 300\,H\rho$ ev. On substitution of the values, we obtain $p = 48\ mc$, where $m$ is the mass of the electron. From the work of Williams and Terroux[5] the primary ionization has been found to vary as $\beta^{-1{\cdot}4}$, where $\beta = v/c$. They give the primary ionization density for an electron of velocity $0{\cdot}96c$ as 22 ions/cm. in air. Thus for the incident particle

$$\beta = 0{\cdot}96(22/106)^{1/1{\cdot}4} = 0{\cdot}31.$$

$$\text{But } p = M\beta c/\sqrt{1-\beta^2} = 48\ mc,$$

where $m$ is the mass of the incident particle.

$$\text{Hence } M = 48\,m.\sqrt{1-\beta^2}/\beta = 147\text{ cm.},$$

on substituting the value of $\beta$. The mass of the incident particle is thus in fair agreement with the mass of the meson, obtained by different workers. Further work is in progress.

## Vapour Pressure of Solids at Low Temperatures (and the Origin of the Planets)

IN a letter on the origin of the solar system, in *Nature* of January 29, Dr. Harold Jeffreys speaks of the importance of estimating the vapour densities of ordinary solids at the hypothetical temperatures of the condensation of the planets; the problem, as he puts it, being largely whether a gas at some not very small fraction of $10^{-15}$ density can condense at 400° A.; he adds that he has not been able to find data on the subject.

In the past, during studies of theist cosmology, I made an estimate of the vapour density of iron, which is no doubt the least easily condensed of the substances significant in the planetary matter, finding it to be about $10^{-44}$ at 273° A., and the temperature for saturation at the sort of density of iron supposed to exist in galactic space ($10^{-29}$) to be about 400° A. Much rougher corresponding values for calcium oxide, based on a boiling point estimated as best one could, were $10^{-113}$, and 1400° A.

In the foregoing the latent heat of vaporization was assumed to be constant, but a more accurate estimate (yet not differing widely from the other) is obtained as follows:

Iron will probably have closely the normal 'Trouton quotient', 21, as mercury has: hence its molecular latent heat at its boiling point (2723° A.) will be 2,723 × 21 = 57,183 cal. Now while the molecular (specific) heat of the monatomic gaseous iron will not change much with temperature, that of the solid is known to increase between 273° A. and 1273° A., as if to become trebled* at 2723° A.: so that, in the Clausius-Clapeyron equation $d\log_e p/dT = L/RT^2$, we add to $L$ (= 57,183) the difference between the heat capacities of the gas and the solid (or liquid) between the two temperatures considered (which is $14{,}250 - \frac{0{\cdot}00465\,(T-273)^2}{2}$). Then

$$\log_e \frac{p \text{ at } 2{,}723^\circ}{p \text{ at } 273^\circ} = \frac{1}{R}\left[\frac{-57{,}183}{T} + \frac{14{,}250}{T} - 0{\cdot}00465\left(T - 546\log T - \frac{78{,}000}{T}\right)\right]_{T=273^\circ}^{T=2{,}723^\circ}.$$

$$= 119 - 5{\cdot}7 + 2{\cdot}9 - 0{\cdot}6 = 115{\cdot}6;$$

whence the vapour pressure at 273° A. is $10^{-50{\cdot}26}$ atmospheres, corresponding to a density of $1{\cdot}3 \times 10^{-53}$, while the temperature of condensation at a density

* *Note added in proof.* 'More than doubled' is perhaps nearer the case; however, a factor of only one and a half would be sufficient.

$10^{-x}$ is roughly $273 \times (53/x)^2$, that is, 910° A. at a density $10^{-16}$ (500° A. at $10^{-29}$).

It is evident, of course, that 'earthy' substances would condense very much more easily still.

As the error in the 'Trouton quotient' is most unlikely to be greater than 10 per cent (which makes an 8 per cent error in the index of the result), and an error of as much as 50 per cent in the specific heat makes only a 10 per cent error in that index, the estimates have presumptively considerably more than the accuracy essential to the purpose.

The subject will be discussed more fully elsewhere.

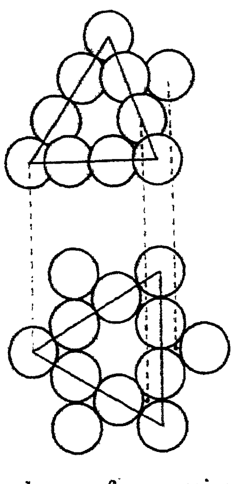
## Open Packing of Spheres

IN their study of the open packing of equal spheres, Heesch and Laves[1] do not consider cases in which the number of spheres with which each sphere makes contact is greater than four; and at first sight it might not perhaps appear worth while to go further, for in the cubic arrangement of spheres which Barlow[2] styled his "second kind of symmetry", each sphere makes contact with six, and it has a density of 0·524.

Another and much more open arrangement with six-point contact is, however, possible; part of this structure is shown in the accompanying figure. For the sake of clearness only the spheres of the initial layer are indicated in the plan. The centres of these spheres lie at the vertices of a plane tessellation of equilateral triangles and hexagons. The spheres of the second layer lie over the centre of alternate triangles of the first layer. The third and all other odd-numbered sheets are congruent with the first but are translated. The fourth and all other even-numbered layers are congruent with the second but are also translated. These translations are of such a kind as cause the spheres of successive sheets to lie on the edges of regular tetrahedra, four spheres on each edge, as shown in the figure. The seventh layer lies over the first.



This structure has a density of 0·370, which must be reckoned remarkably low having regard to the fact that in it each sphere makes contact with as many as six others: it bears comparison with the well-known structure of diamond in which, although each sphere makes contact with only four, the density is 0·338.

## The Perithecial Stage of *Didymella Lycopersici*

THE perithecial stage of the fungus that causes stem rot of tomato was found and described in 1921 by Klebahn[1], who named it *Didymella Lycopersici*. It was apparently not observed again until I found it in October 1943 on a single plant growing at Long Ashton, and since then mature perithecia have been found on three occasions*. Confirmation of the identity of the fungus has been obtained in pathogenicity experiments with single ascospore cultures.

The plant on which perithecia were found in October 1943 was one of a number that had been grown experimentally, out of doors, in pots of soil collected from a field where stem rot had severely attacked two successive crops of outdoor tomatoes. The characteristic basal stem lesion appeared early in August, but it was not until the middle of October that the plant was carefully examined. Pycnidia were then present on the upper part of the lesion; but below them, and down to soil-level, numerous perithecia were present among the disintegrating remains of the cortical tissues. At the end of December 1943, perithecia were found at or near ground-level on a number of plants at Evesham. These plants formed part of a group that had succumbed to artificial inoculation with pycnidial cultures during the summer. In the middle of July last, the perfect stage was again seen on pieces of diseased stems of affected greenhouse plants, collected at the end of May and kept moist on the surface of soil in a pot. The material had been examined from time to time but it was not until the middle of July, by which time the bulk of the cortical tissues had disappeared and only a few fructifications remained, that perithecia were found. Lastly, some diseased outdoor plants, grown from infected seed, were examined at the end of July, and one of them bore perithecia. The perithecia occurred well below ground-level, in a place that must have been approximately at soil level when the plant was in the propagating box. The cortex in this region had entirely disappeared, and scattered perithecia were attached to the woody tissues.

Klebahn[1] stated that perithecia appear after overwintering. His conclusion was based on observations on pieces of diseased stem, exposed in the open during winter, on which perithecia were observed the following April. My observations show that perithecial development is not dependent on an overwintering period, but may occur at any time of year. The constant presence of perithecia near to the soil suggests that moisture supply and, possibly, soil nutrients may be factors governing their formation.

This appears to be the first record of the occurrence of perithecia of *D. Lycopersici* under natural conditions on the host. The observations have largely been confined to outdoor plants, but it is not unlikely that the perithecial stage also occurs on glasshouse plants attacked by stem rot. Notwithstanding the proved viability of the imperfect, pycnidial stage it is possible that perithecia may play a more important part in the survival of the fungus than has hitherto been recognized.

## 'Pasmo' Disease on Wild Flax, *Linum angustifolium*

THE summer of 1944 was outstanding in Ireland with regard to the severity of flax diseases. Both *Phoma* and rust (*Melampsora Lini*) were widespread and virulent, the first mentioned being particularly bad on crops raised from home-saved seed.

During an examination of some species of wild flax as to their probable role in the perpetuation of common flax diseases, a pycnidial fungus was found on the leaves and stems of *Linum angustifolium*; and, on incubating affected material, horn-like tendrils of four-celled spores were extruded from the pycnidia. Morphologically, the causal organism agreed with published descriptions of *Sphœrella linorum*, the cause of 'Pasmo' disease of flax. Using spore suspensions, cross-inoculations on seedlings of *Linum usitatissimum* showed that the disease went over readily to the ordinary flax. Lesions and typical pycnidia containing three septate spores soon developed, and the symptoms on the host here corresponded closely with those described for 'Pasmo' disease. The plants of *L. angustifolium* on which the disease was originally found came from a farm in one of the southern counties. Flax has been cultivated both on this farm and in its vicinity for a number of years, and seed of foreign origin frequently used.

Colhoun and Muskett[1] issued a warning note in *Nature* as to the danger of introducing 'Pasmo' disease into these islands. Although not yet recorded on ordinary flax in Ireland, it is probable that a close inspection of the crop will show this disease to be present. In any event, the indications are that not only has the disease been introduced in the past but also that it has already become established on a native weed. In this connexion it is interesting to note that in New Zealand the 'Pasmo' disease soon after its introduction established itself on *Linum marginale* (an introduced weed), and the disease was afterwards more abundant on this plant than on neighbouring crops of cultivated flax[2].

Incidentally, it may be mentioned that the seedling blight fungus *Colletotrichum linicola* was also found on plants of *L. angustifolium*, and here again cross-inoculations showed the fungus to go over readily to cultivated flax.

## Wilt Disease of Flax in Great Britain

FOR the last three seasons a serious disease has occurred in some experimental plots at Aberystwyth in which oil varieties of flax, *Linum usitatissimum* L., have been grown. *Fusarium Lini* Bolley (*F. oxysporum* Schlecht form *lini* (Bolley) Snyder and Hansen) has been repeatedly isolated from the stems, roots and seeds of the diseased flax plants. This species, first described by Bolley[1] in 1901 as the cause of wilt disease of flax in America and recorded as occurring in Ireland by Pethybridge and Lafferty[2] in 1920, has not previously been reported in Great Britain.

*F. culmorum* (W. G. Sm.) Sacc. has also been found closely associated with *F. Lini* on flax seed. Rost[3] claims that *F. culmorum* causes a foot and root rot of flax and up to 100 per cent loss in germination under adverse weather conditions. In view of this statement further work is in progress on the pathogenicity of this species alone and in combination with *F. Lini*.

The two species of *Fusarium* mentioned above were identified by Dr. W. L. Gordon of the Dominion Rust Research Laboratory, Canada, to whom they were sent through the Imperial Mycological Institute, Kew, and I gratefully acknowledge this assistance.

## Stridulations in the South African Egg-eating Snake, *Daspeltis scaber*, Linn.

MANY strange vocal sounds have been attributed to snakes, but none substantiated. At this Snake Park I have listened carefully both during the day and night, at all seasons and particularly at mating periods, and have never heard any sound other than a hiss. Just recently, however, I observed stridulation in an egg-eater, and have since confirmed this in other specimens.

Normally, the egg-eater is a quite docile snake and can be handled with impunity. An occasional specimen, however, can be easily irritated, when it will throw its body into a series of horseshoe-shaped coils with the head in the centre. By doing this, the scales of any two opposing portions of the body point in opposite directions. The snake writhes its body in such a manner that new coils are continually added on the inside of the horseshoe; at the same time the body is slightly inflated to act as a resonator. In the process of writhing, the tips of the scales rub against each other and produce a rasping sound which is amplified by the inflation of the body. This sound is very similar to a hiss and can easily be mistaken for it. Each spasm of writhing is kept up for only 15–20 sec., and during this time the snake opens its mouth and strikes.

## Meaning and Scope of Social Anthropology

PROF. A. R. RADCLIFFE-BROWN's article in *Nature* of August 26 has just come to my notice, and I hasten, regrettably late I fear, to write to point out that his able exposition of meaning and scope of anthropology does scant justice to Prof. F. C. Bartlett,

whose Huxley Lecture, as I understand it, cannot bear the interpretation placed on it.

Prof. Radcliffe-Brown says that Prof. Bartlett "would give no place in anthropology to archæology, to linguistics, . . . to ethnology . . . or to social anthropology". He must, I think, have misunderstood what Prof. Bartlett said. What Prof. Bartlett did was to advocate a more intensive empirical and, so far as possible, controlled study of the behaviour of contemporary social groups. He stated very clearly in the fourth paragraph of his lecture, as printed in *Nature* (Dec. 18, 1943), that there were many other concerns of anthropology which he hoped would "continue to be studied vigorously". He excluded archæology from anthropology only to the extent of treating it as an aspect of that study which had not "kept close to empirical fact", and he stated specifically that it could be adopted as a line of approach to the four main branches of anthropology which did rely on such "empirical fact". Linguistics I do not think Prof. Bartlett mentioned at all by name, but one must in reason assume them to be one of those unspecified branches of anthropology which he wished to have vigorously pursued; as for ethnology and social anthropology, as defined by Prof. Radcliffe-Brown, I can infer nothing from Prof. Bartlett's lecture except that he regards their study with the greatest approval and appreciation, and is anxious only to "forge a link closer than ever before" between the work of the anthropologist and the psychologist in their pursuit.

Prof. Bartlett is a psychologist and his whole lecture was, naturally, given specifically from a psychologist's point of view, though I doubt if he would endorse the views expressed by Prof. Radcliffe-Brown as to the nature of psychology and 'psychologies'.

## Origin of Semitic Languages

THE mouth gesture theory of the origin of human speech as it is put forward by Sir Richard Paget and by Prof. Alexander Jóhannesson[1] is certainly a valuable contribution to research on the origin of human speech, although it is not favourably regarded by comparative linguists to-day. It seems that they want to leave the matter to the anthropologists, who are beginning to show considerable interest in it.

A predecessor of Sir Richard Paget and Prof. Jóhannesson was the philosopher Schopenhauer. In his "Psychological Observations" he writes[2]:

". . . Natural gesticulation such as commonly accompanies any lively talk, is a language of its own, more widespread even than the language of words—as far, I mean, as it is independent of words and alike in all nations."

". . . As I have said, the most interesting and amusing part of the matter is the complete identity and solidarity of the gestures used to denote the same set of circumstances even though by people of different temperament, so that the gestures become exactly like words of a language alike for every one. . . . And yet there can be no doubt but that these standing gestures which everyone uses are the result of no convention or collusion. They are original and innate—a true language of nature. . . ."

Schopenhauer, however, makes a proviso:

". . . Strictly speaking, what I get from gesticulation alone is an abstract notion of the essential drift of what is being said. . . . It is the quintessence, the true substance of the conversation and it remains identical no matter what may have given rise to the conversation or what it may be about."

I have tried, in a work as yet unpublished, to reconstruct in another way the origin of human speech and to demonstrate the identity of the Indogermanic and Semitic languages. I do it with the help of the facts of physiology, of 'animal languages', the 'language' of the suckling and the psychology of primitive men. It was possible to deduce most of the words of the Indogermanic and Semitic languages from this reconstructed first language.

A combination of the two theories may perhaps help to further progress and to shed more light on the origin of the most human faculty of human beings.

## First Use of Current-Bedding to Determine Orientation of Strata

IN a recent letter[1], Dr. Archie Lamont directed attention to John Kelly's account, published in 1864, of the use of current-bedding to decide which way up strata were lying. Kelly gave the credit for the discovery of the method to Patrick Ganly. Ganly had given a description of it to the Geological Society of Dublin in 1856[2], but he had been using it much earlier.

Recently, three volumes of letters on geological subjects written by Patrick Ganly to John Kelly and Richard Griffith between 1838 and 1848 have come to light among the records in the Valuation Office in Dublin. These are at present deposited in the library of the Royal Irish Academy, through the courtesy of the Commissioner of Valuation. In one of the letters, dated June 18, 1838, from Dingle, and in another, dated July 16, 1838, from Glengarriff, he uses the method to work out the local structures. Both letters are accompanied by sketches of current-bedding. In the first case he deduces an inversion in the Dingle Beds at Fahan, and in the second shows that in passing from the Red Slate Series to the Black Slate Series (from the Old Red Sandstone to the Carboniferous Slate) south-east of Glengarriff, "the natural order of the succession of the strata accords with their present order of superposition".

Ganly was one of the boundary surveyors engaged on the Griffith Valuation of Ireland. He was employed by Griffith on geological work, and his surveys seem to have been the basis of much of the revision of the later editions of Griffith's geological map of Ireland, first published in 1838.

# PROGRESS OF GEOLOGY IN THE U.S.S.R.

SOVIET writers have good cause for satisfaction in the achievements of their country in the field of geology since the Revolution of 1917. This justifiable self-satisfaction has a less justifiable corollary in the constant emphasis on the backwardness of pre-Revolutionary Russia. The pace of scientific progress has increased everywhere in the last few decades, both from its own momentum and because of the vast increase in the number of workers in the field; but this should not detract from our appreciation of the worth of earlier patrons and scholars working in less favourable circumstances.

Russia could boast a mineralogical museum, of a sort, as early as 1716. It was founded by Peter the Great, who was also responsible for the start of a systematic survey of the Russian Empire. By the middle of the century, the great Russian scientific worker M. V. Lomonosov (1711–65) was actively engaged in geological work, and later in the same century, in 1773—a date at which no similar institution existed in Great Britain—the Mining Institute of St. Petersburg was founded. It is true that in the eighteenth century and even later the bulk of the geological work in Russia was carried out by foreigners, among whom the name of Sir Robert Murchison is outstanding. Gradually, however, the Russian geologists asserted themselves and a number of them achieved recognition in the international sphere. Such were A. A. Inostranzev, I. V. Mushketov, M. V. Pavlov, A. P. Karpinsky, E. S. Fedorov, F. Y. Loewinson-Lessing and many others. It is claimed, however, that the progress made during the past twenty-five years exceeds by far all previous achievements. This is probably true, if one considers the scale of the geological research and the number of workers engaged. It is estimated that in 1914 no more than three hundred professional geologists existed in Russia, and that vast territories such as Siberia, Central Asia and the Caucasus were served by only a handful of men. Although it is impossible to estimate the present numbers engaged in geological work in the U.S.S.R., it must be at least ten times as large. At the last International Geological Congress held in Moscow in 1937, the Russian membership exceeded 1,500 members, and this figure did not include many junior workers.

This Congress and the recently published book[1], which is the main subject of this review, must be taken together as an attempt to make widely known the results of a quarter of a century of endeavour in the field of geology (and the kindred sciences of mineralogy and petrology) and the stages by which those results were achieved. The Congress aimed mainly at the enlightenment of non-Russian men of science; on those who were fortunate enough to be present in Moscow and on the elaborate field excursions it will leave an indelible impression. For those who have no such personal recollections, the guide-books and published abstracts of papers provide no adequate substitute. On the other hand, the collection of twenty-five articles on the various branches of geology which comprise the "Progress of Geological and Geographical Sciences in the U.S.S.R. during Twenty-five Years" are very full and well documented, but they are in Russian.

Each article is the work of a prominent authority on its subject, and the whole collection is edited by the veteran Russian geologist V. A. Obruchev. All branches of geology are represented (including one article on geography) with the exception of palæophytology and the regional geology of European Russia, which are missing because the War has absorbed the energies and the time of the men who were to have been responsible for them. It is impossible in this review to give an adequate exposition of the book, but it may be useful to indicate some of its most important points.

First come the articles dealing with the progress made in mineralogy and petrology. These are very informative and they provide a good account of the work of different research schools, such as that on crystal optics originated by E. S. Fedorov, physico-chemical analysis by N. S. Kurnakov, mineral synthesis by D. P. Grigoriev and geochemistry by V. I. Vernadsky and A. E. Fersman. In petrology, naturally, the name of F. Y. Loewinson-Lessing comes first, but much has been achieved by many other petrologists—D. S. Belyankin, B. M. Kupletsky, V. N. Lodochnikov, A. N. Zavarizky and others. The Petrographical Institute founded in 1931 is in a way unique in the whole world, and in the short period of its existence has published, besides the periodical *Travaux de l'Institut Petrographique*, a great number of monographs on the regional petrography of the U.S.S.R., on various rocks and rock-forming minerals. Technical petrology is also extremely well developed in the U.S.S.R., and a number of workers are engaged on the study of slags, cements, fire-resisting materials, glass and cast basalt.

The articles dealing with the progress of palæontology are rather short. On the other hand, those on stratigraphy are the longest and the most valuable of the book. The industrial prospecting for coal, oil and bedded ores is no doubt partly responsible for the progress made in these branches of geology, and it is significant that the greatest amount of work has been done in the study of Carboniferous and Tertiary rocks, the main sources of coal and oil. This does not preclude the achievement made in the study of other systems, and geological mapping and surveying is constantly on the increase all over the territory of the U.S.S.R., but more particularly in the Urals, Siberia, Central Asia and the Caucasus. During this new survey, many startling discoveries have been made, discoveries which have often led to a complete revision of previously accepted knowledge. Stratigraphical work nearly always involves tectonics, and the technique of tectonic investigation recently developed in western Europe and the United States has been applied with the greatest effect by Russian workers. The major tectonic problems, sometimes called geotectonics, have received a good deal of attention, and as so often happens have become involved in a tangle of conflicting hypotheses of a highly speculative nature. For example, a well-known Russian geologist, M. M. Tetiaev, raised a storm recently by a hypothesis which postulates that the tectonic movements are mainly due to the expansion of the earth's interior, and that the folded mountains are due to the pressure exercised by the expanding core against the rigid earth's crust. Many other tectonic hypotheses have been proposed and demolished.

The remaining articles deal with the progress made in engineering geology, applied geophysics, the study of permanently frozen ground, the study of coal, oil shales and oil, and geography. Particularly interesting are articles describing the two new geological museums: the Chernyshev Central and Prospecting

Museum at Leningrad, opened in 1931 and containing collections illustrative of the progress of the geological survey of the U.S.S.R.; and the Karpinsky Geological Museum at Moscow, opened in 1934 and containing 72,250 specimens of minerals. These are arranged in five separate collections: systematic, geochemical, genetic, crystallographic and applied. Another interesting aspect of the status of geology in the U.S.S.R. is the establishment in 1920 of the Ilmen National Park in the southern Urals for the preservation and study of the famous mineral localities of precious stones and other minerals as well as flora and fauna.

The progress made in the U.S.S.R. in the utilization of mineral wealth is described independently in a short article by V. I. Kryzhanovsky[2], in which he gives a review of the achievement in the exploration and utilization of various ores. Only a few outstanding examples can be given here: the discovery of very rich iron ore at Magnitogorsk in the southern Urals, nickel and titanium in the southern Urals and Kola peninsula, molybdenum and tungsten ores in Siberia and Central Asia, bauxite at Tichvin (near Leningrad) and the Urals, tin ore (previously unknown in the U.S.S.R.) in Central Asia. There is also a description of the progress made in the prospecting and mining of gold, platinum, uranium, radium, manganese, coal and oil, borates, etc. But probably the most spectacular discoveries are those of apatite in the Kola peninsula and potash salts in the Urals, both of them of great importance in agriculture. The apatite deposits of the Kola peninsula, discovered in 1921, are the richest in the world, with an estimated reserve of 2,000 million tons. Since this discovery, a new industrial area with two new thriving towns has sprung up in a previously deserted arctic tundra. Besides apatite, a number of other minerals were discovered in the Kola peninsula, such as nepheline, pyrrhotite, titanium ores, ores of rare elements, kyanite, garnet, etc.

The discovery of potash salts at Solikamsk in the northern Urals is no less spectacular. The reserves of sylvite at Solikamsk are estimated to be five times greater than those at Stassfurt in Germany, hitherto regarded as the richest deposit in the world, and still more deposits are being discovered as the survey progresses.

The mineral wealth of the U.S.S.R., always known to be enormous, is rapidly coming within reach of the miner and thus provides a solid foundation for an ever increasing industrialization. The contributions made by geologists and miners to the defence of their country are thus inestimable. S. I. TOMKEIEFF.

## CHEMISTRY IN RELATION TO MEDICINE

IN a recent lecture before the Royal Institute of Chemistry* on some recent advances in chemistry in relation to medicine, D. H. Hey gives an interesting and concise account of the astonishing contributions which have been made in this field during the last ten years. The beginning of this century saw the introduction of the first therapeutic compound of major importance which had been made to the chemist's design, namely, aspirin, first made in 1899. At the present rate of progress, Dr. Hey suggests, the present major diseases and scourges of mankind will be completely controlled well before the end of this century. This will seem to some medical men an optimistic prophecy; but certainly recent work gives every reason to hope for its realization. One difficulty, however, is that the human talent which slays these dragons so rapidly discovers almost as quickly new causes of disease which defeat existing remedies; and although we may banish the major scourges, we should give equal attention to the minor ones, some of which cause incalculable unhappiness and economic loss and are untouched by our most efficient therapeutic compounds—the 'common cold', for example.

Dr. Hey deals with the sulphonamides, the amidines, the antibiotics (such as penicillin) and the steroid hormones (testosterone, œstradiol and progesterone). "It is no exaggeration to say that the new sulphonamide derivatives prepared during the last seven or eight years can be numbered by the thousand, but the vast majority of these have never been tested *in vivo*". The author explains how the chemist has juggled with the sulphonamide hydrogen atoms in the sulphonamide molecule to produce sulphapyridine, sulphathiazole and other compounds which are now being widely used, and he discusses the properties and bacteriostatic actions of these.

The history of the development of the amidines illustrates the tortuous paths by which final success is sometimes attained. Hey traces the origin of the work on the amidines to an early observation by Koch on parathyroid tetany. Methylguanidine was found in the urine of animals suffering from this, and it was found that administration of methylguanidine or of guanidine caused a fall in blood sugar. Guanidine compounds of greater activity but less toxicity were then sought out, and synthalin and synthalin B were introduced for the oral treatment of diabetes; but they caused too much damage to the liver. It was also found that trypanosomes consume, in artificial cultures, large quantities of glucose, and it was hoped that synthalin, by reducing the blood sugar, would interfere with the development of the trypanosomes and so would be useful for the treatment of sleeping sickness. Lourie and Warrington Yorke found that it did affect the trypanosomes, but not because it reduced the blood sugar but because it was trypanocidal, while insulin was not. This led to the discovery of less toxic drugs of this type, some of which have been tried for the treatment of trypanosomiasis and also, by virtue of their antibacterial action, for the treatment of burns and wounds. *The Lancet* (796, June 17, 1944), for example, discusses the use of propamidine (4 : 4′-diamidinodiphenoxypropane) for the treatment of sepsis in burns and wounds, pointing out that the work of F. R. Selbie and J. McIntosh (*J. Path. and Bact.*, 55, 477; 1943) and of J. W. Allen, F. Burgess and G. R. Cameron (*ibid.*, 56, 217; 1944) and of others indicates that the toxicity of this drug requires care in its use and selection of suitable cases. *The British Medical Journal* (725, May 27, 1944) discusses the relative advantages and disadvantages of the diamidines and antimonial compounds for the treatment of kala-azar and gives further references to the literature about them.

* "Some Recent Advances in Chemistry in Relation to Medicine". By Dr. D. H. Hey. Pp. 24. (London: Royal Institute of Chemistry, 1944.)

The blood anti-coagulants heparin and dicoumarin provide an equally interesting story. People receiving large and continued doses of salicylates should also receive vitamin $K_1$ or some related compound which will, by maintaining the synthesis of prothrombin in the blood, counteract the anti-coagulant action of salicylic acid due to its reduction of prothrombin. The fact that dicoumarin can be degraded to salicylic acid completes the story.

The author's treatment of the genital hormones is no less interesting and illuminating. The diagrams of the molecular structure of the compounds described help the inexpert reader very considerably.

G. Lapage.

## RADIO PLANNING IN THE U.S.A.

The present War has been accompanied by great advances in the application of radio technique to communications and other purposes, and much thought is already being given to the conversion of the results of this work to peace-time conditions. Among the major problems of a post-war world will be the allocation of different portions of the radio-frequency spectrum among the various interests involved, and the consideration of the trend of broadcasting with both amplitude and frequency modulation, and of television. In the United States of America, the body responsible for frequency allocation and for controlling the standards used in the systems developed for the various radio services is the Federal Communications Commission; and in November 1942 the chairman of the Commission, Mr. J. L. Fly, suggested that an organization representative of the radio industry and of the personnel involved therein might be set up to consider the technical requirements of the future in the field of radio. Accordingly, a Radio Technical Planning Board (R.T.P.B.) was set up during 1943; and an account of the organization and work of this body to date has been given by its chairman, Dr. W. R. G. Baker, in the June issue of the *General Electric Review* (U.S.A.).

The objectives of the Board are stated to be the formulation of sound engineering principles and the organization of technical facts which will assist in the development, for the public interest, of the radio industry and the radio services of the nation. The sponsors of the Radio Technical Planning Board are those non-profit-making associations and societies which have an important interest in radio and which indicate a willingness to co-operate in achieving the objectives of the Board. At the present time, there are twelve such bodies which contribute an annual sum of 1,000 dollars or more towards the expenses of the Board, while in addition, there are six non-contributing sponsors.

The article referred to above contains an illustrated detailed account of the organizational structure of the Board and its constituent panels, involving a total personnel of about six hundred at the present time. Under the staff and administrative committee, thirteen panels have been set up to deal with subjects covering the whole field of radio communication, broadcasting, television, facsimile, navigation and the use of high-frequency equipment for industrial, medical and scientific purposes. Each panel is under the chairmanship of a leading engineer in the particular branch of radio concerned, and he is assisted by the most competent specialists available.

An illustrated coloured chart accompanying the article shows that the frequency spectrum with which the Radio Technical Planning Board is concerned extends from 40 kilocycles per second to at least 500 megacycles per second. In view of this broad field, and the number of individuals involved, it is perhaps unlikely that there will be a preponderance of unanimous recommendations emanating from the work of the Board. Even in the absence of very many strong majority proposals, it is considered that the work of the Board will serve a useful purpose in bringing to light many controversial points and in amassing and disseminating a large amount of technical data and information which will be of undoubted value in the planning of radio applications after the War.

## THE NILE BASIN

In recent years the Egyptian Government has published various monographs dealing with the Nile and its waters, including Dr. J. Ball's "Contributions to the Geography of Egypt". Now Dr. H. E. Hurst, director-general of the Physical Department, has compiled a general non-technical account of what is known of the Nile basin and the floods of the Nile, as well as an account of the various barrages*. The publication is well illustrated by one coloured and several black and white maps and diagrams. There is, however, no bibliography.

The Nile basin, embracing about one tenth of the area of Africa, extends far beyond the confines of Egypt; but its most important aspects are peculiar to Egypt and the Anglo-Egyptian Sudan. A brief historical survey might perhaps have stressed how near the truth Ptolemy came regarding the sources of the Nile, though he was largely discredited until the end of the nineteenth century. The physical history of the river is sketched and Ball's hypothesis of Lake Sudd is discredited. The discovery of flint implements a few metres above the present level of the river at Khartoum is a blow to the theory of a lake which existed until a late date, when it was supposed to have overflowed to the north and joined the Bahr-el-Jebel and Blue Nile waters to the Nile. The distribution of early implements suggests that the stone people of the Nile valley probably lived in a warm and humid climate. Since that climate changed to its present character, Dr. Hurst believes that there is no evidence of periodic changes, though there are irregularities from year to year. Nor does he find any connexion, which has been suggested, between sunspot activity and Nile flow or the level of Lake Victoria.

While the hydrology of the Nile is fairly well known, there is still a little uncertainty about the origin of the rainfall which causes the floods. Abyssinia provides 84 per cent of all Nile water and 70 per cent of flood water; but the old theory that this water originates from the Indian Ocean monsoon seems to be fallacious. Rainfall on the east and south of the Abyssinian plateau is scanty compared with that on the west, to which, in the flood season, the winds blow across Africa from the Gulf of Guinea. It seems

* Ministry of Public Works, Egypt: Physical Department Paper No. 45. A Short Account of the Nile Basin. By Dr. H. E. Hurst. Pp. iv+77+9 plates. (Cairo: Government Press, 1944.) P.T.40.

probable therefore that the flood waters which irrigate Egypt originate in the Atlantic. The small contribution which the rain of the Lake Plateau makes to the Nile flow is put at about 16 per cent of the total flow. The Blue Nile is the great feeder, but the importance for this river of Lake Tana has been exaggerated; other tributaries are more important than the one draining Tana. The waters of the White Nile are dammed up by those of the Blue Nile when the latter is in flood, and much of the White Nile waters then, as at other times also, is lost by evaporation.

Dr. Hurst concludes with some suggestions for improving control of the river. The amount of water lost by evaporation in the Bahr-el-Jebel swamps is enormous. Possible ways of preventing this loss are either by the embankment of the Jebel and the Zeraf to prevent the spilling of water into the marshes, or the construction of a new straight channel outside the swamps into which the flow could be diverted. The loss of water on the Bahr-el-Ghazal Basin also calls for preventive measures. There is also the problem of constructing a dam below Lake Albert in order to use that lake as a storage reservoir. Another among the schemes touched on is the proposal for a power-station at the Aswan Barrage.

## PROCEEDINGS OF THE ZOOLOGICAL SOCIETY OF LONDON

IN the current number of the *Proceedings of the Zoological Society*, comprising Parts 1 and 2 of Volume 114, the division into two series (A and B) has been discontinued. Accordingly, all papers will now be published in a single annual volume, containing four parts. The issue of the *Proceedings* in three series, (A) General and Experimental, (B) Systematic and Morphological, and (C) Abstracts of papers communicated at the scientific meetings, was introduced in 1937, and at the same time the practice of giving a serial number to each volume. Previously the volumes were referred to only by the year of issue, which occasionally introduced some uncertainty about the date of publication, since the last part of the volume for any particular year might not appear until January or February in the following year. A further complication arises as a result of the large number of pages contained in the *Proceedings* of some particular years, which necessitated their being bound in two volumes, and title pages and contents sheets were supplied for this purpose. It thus became necessary to refer to the first or second 'volume' of each year of issue. The use of a serial volume number, which will be printed on all future parts, will obviate this necessity, and simplify bibliographic references to publications in the *Proceedings*.

The present number comprises ten papers dealing with a wide variety of subjects. F. W. Rogers Brambell has a paper on the reproduction of the wild rabbit, *Oryctolagus cuniculus* (L.), based on the examination of 957 males, 1,529 females and 1 inter-sex, obtained in Caernarvonshire between February 1941 and June 1942. A very interesting problem arises in connexion with the pre-natal mortality. It is estimated that at least 60 per cent of litters conceived are lost owing to the death and reabsorption of all the embryos, the majority of which die on or about the twelfth day. The mean number of young born to each adult female is found to be between 10·35 and 11·70 per annum. Ti-Chow Tung and Yu Fung-Yeh Tung give an account of experiments supporting their view that in the goldfish, *Carassius auratus*, there exists some centre comparable to the amphibian grey crescent from which the organizer region later arises. R. I. Pocock discusses the races of the North African wild cat. E. J. Popham describes the changes in an aquatic insect population produced by using minnows as predators. A significant difference between the population of three Corixids collected each week was observed, and after the introduction of the minnows the relative proportions of Corixids adapted to the background increased. Robert Gurney deals with the systematics of the crustacean genus *Callianassa*, and G. H. Findlay describes the development of the auditory ossicles in the elephant shrew, the tenrec and the golden mole. G. P. Wells has a paper emphasizing the inadequacy of our knowledge of even the commonest laboratory animals. The neuropodia and notopodia of *Arenicola marina*, L., are described in detail, and for working out the anatomy of the intricate musculature the use of polarized light is recommended. L. S. Ramaswami gives an account of the heart and associated vessels in some genera of *Apoda*, and V. V. Tchernavin gives a revision of the subfamily Orestiinæ and a revision of some Trichomycterinæ, including descriptions of new species based on material preserved in the British Museum, a great part of which was collected by the Titicaca Expedition, of the species of these little-known groups of freshwater fishes.

## RUSTY WATER AND MOSQUITO BREEDING

WE have received a report by Mr. K. B. Williamson, malaria research officer, Penang (c/o Ross Institute of Tropical Hygiene, London School of Hygiene and Tropical Medicine, W.C.1), on an "Investigation of Ferruginous Waters in relation to the Breeding of Malaria-carrying Mosquitoes". It is a common observation among malariologists in the tropics that waters containing rusty deposits or bearing iridescent surface films of precipitated iron are generally free from mosquito larvæ, and the possibility of utilizing this fact for the control of mosquito breeding has often been mooted. But exact information about the composition of waters of this kind and about the source of the iron has been wanting. Mr. Williamson's report is based on the examination of various types of rusty waters on Hampstead Heath and elsewhere in the neighbourhood of London and around Malvern, as well as upon his experiences in Malaya. It deals mainly with questions of chemistry.

Iron occurs in water: (1) in particulate form as colloidal ferric hydroxide ('iron rust'), the particles being so small that the water is quite clear; it is this colloidal iron which is unstable and readily gives rise to solid aggregates in the form of surface films or precipitates; (2) in true solution as ionized salts of ferrous or ferric iron; (3) as non-ionized organic complexes.

The humic matter derived from the slow rotting of excess vegetation present in soil combines with both ferrous and ferric iron and exerts a stabilizing influence on the colloidal ferric oxide. Humic matter is itself antagonistic to the breeding of most species

of malaria-carrying mosquitoes. Excess of rotting vegetation in contact with the soil will thus exert a dual benefit.

A provisional attempt has been made to classify ferruginous waters. A ferruginous water is defined as one that contains a minimum of two parts per million of iron in solution or colloidal suspension. Many so-called 'rusty' waters show merely a deposit of rust-coloured sediment which has been thrown down at an earlier date; a deposit of this kind affords no proof that the water continues supercharged with iron. On the other hand, superficial films of 'rust' supply a more immediate indication of the presence of an unstable excess of iron in water. Such iron may be derived (i) from underground mineral sources such as pyrites, (ii) from vegetation rotted under anaerobic conditions in marshy soil, the iron-containing humus forming organic complexes with the iron present in the superficial soil, or (iii) in small amount, from the rotting of vegetation alone in the water.

On the biological side the work is incomplete. Observations on the natural fauna and flora of ferruginous waters have been rather limited; but such waters are characterized by an almost complete absence of water insects, aquatic helminths, Crustacea and Algæ. It has been found by experiment that mosquito larvæ (*Anopheles maculipennis* var. *atroparvus*), newly hatched from the egg, are unaffected by the iron-containing waters provided they are fed; but when placed in samples of such waters without added food they soon die of starvation. It is, therefore, concluded that mosquito larvæ fail to develop in rusty water from lack of food, which is ascribed in the main to the inimical effects of colloidal iron upon the growth of Algæ, Protozoa and other micro-organisms. There is no evidence that iron-containing surface films will suffocate the larvæ.

## FUEL RESEARCH

THE Melchett Lecture for 1944 of the Institute of Fuel was delivered on October 12 by Dr. J. G. King on the "Pattern of Fuel Research". Under this title he gave an account of the progress of fuel research seen as a whole, with main branches and subsections fitting together into patterns although the work may have been done in many places, by various organizations and individuals.

The three main patterns chosen were the hydrogenation, the gasification and the study of the constitution and properties of coal. Dr. King gave a survey of the development, from the first observations of Bergius in 1912, of the hydrogenation of solid coal, of the liquid products of carbonization and of petroleum. Actually the conversion of solid coal to liquid fuels ranging from heavy oil to light spirits and hydrocarbon gases involves an interwoven sequence of stages. Behind the large-scale operations now in use stands an immense volume of patient experiment to fix the choice of catalysts, temperature, pressure and other conditions necessary for success, some of which has been done at the Fuel Research Station under Dr. King's direction.

The carbonization of coal in ovens or retorts carries the limitation that only about one fourth of the raw coal can be recovered in the gaseous form. By gasification in the gas producer, it is possible to recover nearly all the fuel in a fluid form but unsuitable for public supply. It came to be recognized that by substituting oxygen for air and working at pressures above atmospheric, the products of gasification could be modified in chemical composition to give a product more suited for public distribution. It happens that in our generation, the technique of oxygen production has so developed as to make it possible to use oxygen in fuel manufacture—at least in some countries. In Great Britain the Joint Research Committee of the Institution of Gas Engineers and the University of Leeds has pursued the problems involved for nearly ten years. It is found that a range of technique is possible, from direct hydrogenation of coal to methane, reaching to a synthesis of methane from the product of pre-gasification of coke by oxygen and steam. These investigations are now in the stage of large-scale operation. In the long run, the successful achievement of this part of the pattern of fuel research can have far-reaching effects.

Dr. King's third main branch of the pattern covers the study of coal constitution and properties both physical and chemical. This includes the immense volume of work done in laboratories all over the world. It would appear that the results of this work, though marked often by ingenuity and industry, have been, in the main, of academic value only, and no clear pattern is revealed. It is thus unlike the first two branches, which concern themselves with the developments of processes. The study of constitution and properties must, however, be of assistance to them.

Dr. King's lecture can be commended as an excellent picture of the pattern of current research on fuel.

## FORTHCOMING EVENTS

### Saturday, December 2

INSTITUTE OF PHYSICS (LONDON AND HOME COUNTIES' BRANCH) (at the Royal Institution, Albemarle Street, London, W.1), at 2 p.m. —Conference on "The Selection and Training of Personnel for Industry" (to be opened by Major F. A. Freeth, F.R.S.).

GEOLOGISTS' ASSOCIATION (at the Geological Society of London, Burlington House, Piccadilly, London, W.1), at 2.30 p.m.—Dr. G. M. Lees: "The Geology of the Oilfields of the Middle East".

SHEFFIELD METALLURGICAL ASSOCIATION (joint meeting with the IRON AND STEEL INSTITUTE and the SHEFFIELD SOCIETY OF ENGINEERS AND METALLURGISTS) (at the Royal Victoria Station Hotel, Sheffield), at 2.30 p.m.—Discussion of Papers presented to the Iron and Steel Institute.

### Monday, December 4

ROYAL SOCIETY OF ARTS (at John Adam Street, Adelphi, London, W.C.2), at 1.45 p.m.—Dr. S. K. Kon: "Milk", (3) "Milk in relation to Human Nutrition—Recent Aspects" (Cantor Lecture).

FARMERS' CLUB (at the Royal Empire Society, Craven Street, Strand, London, W.C.2), at 2.30 p.m.—Mr. H. R. Davidson: "Pigs in the Long Range Policy".

ROYAL GEOGRAPHICAL SOCIETY (at Kensington Gore, South Kensington, London, S.W.7), at 5 p.m.—Dr. J. K. St. Joseph: "Air Photography in Archæology".

SOCIETY OF ENGINEERS (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Mr. E. S. Waddington: "The Welding of Aluminium"; Dr. H. G. Taylor: "Light Alloy Welding".

### Tuesday, December 5

ROYAL ANTHROPOLOGICAL INSTITUTE (at the Royal Geographical Society, Kensington Gore, London, S.W.7), at 1.30 p.m.—Mrs. Olive Murray Chapman: "A Journey across Madagascar".

BRITISH SOCIETY FOR INTERNATIONAL BIBLIOGRAPHY (at the Institution of Electrical Engineers, Savoy Place, Victoria Embankment, London, W.C.2), at 2.30 p.m.—Mr. W. C. Cooper: "The Classification and Indexing of Technical Aeronautical Information"; Dr. J. A. Wilcken: "Abstracting, Indexing and Classification".

ROYAL INSTITUTION (at 21 Albemarle Street, Piccadilly, London, W.1), at 5.15 p.m.—Sir Henry Dale, O.M., G.B.E., Pres.R.S.: "Modern Developments in Chemical Therapeutics", (i) "Beginnings of Chemotherapy".

INSTITUTION OF CIVIL ENGINEERS (STRUCTURAL AND BUILDING ENGINEERING DIVISION) (at Great George Street, Westminster, London, S.W.1), at 5.30 p.m.—Prof. A. J. Sutton Pippard and Letitia Chitty: "Some Problems presented by Cable Bracing".

QUEKETT MICROSCOPICAL SOCIETY (at the Royal Society, Burlington House, Piccadilly, London, W.1), at 7 p.m.—Exhibits.

### Wednesday, December 6

ROYAL SOCIETY OF ARTS (at John Adam Street, Adelphi, London, W.C.2), at 1.45 p.m.—Dr. C. A. P. Southwell: "Petroleum Production in England".

GEOLOGICAL SOCIETY OF LONDON (at Burlington House, Piccadilly, London, W.1), at 2.45 p.m.—Dr. George Martin Lees: "The Geology of the Oilfields in Great Britain".

GEOLOGICAL SOCIETY OF LONDON (at Burlington House, Piccadilly, London, W.1), at 3 p.m.—Scientific Papers.

ROYAL ENTOMOLOGICAL SOCIETY OF LONDON (at 41 Queen's Gate, South Kensington, London, S.W.7), at 3.30 p.m.—Dr. C. B. Williams: "A Recent Entomological Tour of South America on behalf of the British Council".

INSTITUTION OF ELECTRICAL ENGINEERS (RADIO SECTION) (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Dr. L. Essen: "The Measurement of Balanced and Unbalanced Impedances at Frequencies near 500 Mc/s and its Application to the Determination of the Propagation Constants of Cables".

ROYAL PHOTOGRAPHIC SOCIETY (SCIENTIFIC AND TECHNICAL GROUP) (joint meeting with the KINEMATOGRAPH SECTION and the BRITISH KINEMATOGRAPH SOCIETY) (at 16 Princes Gate, South Kensington, London, S.W.7), at 6 p.m.—Discussion on "Photographic Aspects of Sound Recording".

### Thursday, December 7

ROYAL INSTITUTION (at 21 Albemarle Street, Piccadilly, London, W.1), at 2.30 p.m.—Prof. James Gray, F.R.S.: "Locomotory Mechanisms in Vertebrate Animals", (iii) "Locomotory Mechanism in Typical Tetrapods—Limbs as Co-ordinated Struts and Levers".

CHEMICAL ENGINEERING GROUP (joint meeting with the INSTITUTION OF CHEMICAL ENGINEERS and the BRISTOL SECTION OF THE SOCIETY OF CHEMICAL INDUSTRY) (in the University Chemical Department, Woodland Road, Bristol), at 5.30 p.m.—Mr. R. T. Pemberton: "Ion Exchanges Applied to Water Treatment".

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Mr. G. A. Juhlin: "Standardization and Design of A.C. Turbo-Type Generators".

### Friday, December 8

ASSOCIATION OF APPLIED BIOLOGISTS (at the Imperial College of Science, South Kensington, London, S.W.7), at 11.30 a.m. (in the Botanical Lecture Theatre)—Mr. T. Goodey: "Eelworm Disease of Onions—Some Recent Investigations"; at 2.15 p.m. (in the Metallurgical Lecture Theatre)—Mr. F. R. Petherbridge: "The Biology and Control of the Carrot Fly"; Mr. A. Roebuck: "The Carrot Fly in the Midlands"; Mr. G. Fox-Wilson: "Investigations into the Control of the Carrot Fly under Garden Conditions".

INSTITUTE OF FUEL (SOUTH WALES SECTION) (at the Engineers' Institute, Cardiff), at 4.30 p.m.—Mr. J. O. Samuel: "The Application of Flocculation and Flotation Principles to the Recovery of Low Grade Fuel".

ROYAL ASTRONOMICAL SOCIETY (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Discussion on "Astronomical and Geophysical Periodicities" (to be opened by Dr. Harold Jeffreys, F.R.S.).

ROYAL INSTITUTION (at 21 Albemarle Street, Piccadilly, London, W.1), at 5 p.m.—Lieut.-Colonel E. F. W. Mackenzie: "London's Water Supply—Safeguarding its Purity in Peace and War".

### Saturday, December 9

BRITISH MYCOLOGICAL SOCIETY (in the Department of Biology, Chelsea Polytechnic, Manresa Road, London, S.W.3), at 12 noon.—Annual Meeting; at 2 p.m.—Mr. R. W. Marsh: "Mycological Contacts".

### Saturday, December 9—Sunday, December 10

ASSOCIATION OF SPECIAL LIBRARIES AND INFORMATION BUREAUX (at the Royal Society, Burlington House, Piccadilly, London, W.1).

**Saturday, December 9**

At 11.30 a.m.—Sir Frederic Kenyon, G.B.E., K.C.B.: "Organized Knowledge in the World of the Future".

At 2 p.m.—Symposium on "The Empire Contribution to the Flow of World Information".

At 4.30 p.m.—Mr. G. K. Wilkie: "Trade Catalogues in Commercial Libraries".

**Sunday, December 10**

At 11 a.m.—Mr. Geoffrey A. Shires: "The Technical Information Bulletin and What to Put In It": Mrs. Lucia Moholy: "Developments and Extensions in the Use of Microfilm".

At 3 p.m.—Discussion on "The Status and Education of Special Librarians and Information Officers".

At 5 p.m.—Mr. B. Agard Evans: "Some Aspects of a New Technical Information Service in War-time".

## APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

EDUCATIONAL PSYCHOLOGIST—The Director of Education, County Offices, Oxford (December 8).

SPEECH THERAPIST (full-time)—The Chief Education Officer, County Offices, Chelmsford (December 8).

LECTURER (full-time) IN ELECTRICAL ENGINEERING—The Principal, Technical College, Bradford Place, Walsall (December 9).

ASSISTANT MASTER (full-time) to teach Mechanical Engineering Subjects in the Day School of Engineering and the part-time Day and Evening Engineering Courses—The Principal, Hendon Technical College, The Burroughs, Hendon, London, N.W.4 (December 9).

LECTURER (full-time) IN PHYSICS to B.Sc. Special standard—The Clerk to the Governors, South-East Essex Technical College and School of Art, Longbridge Road, Dagenham, Essex (December 9).

DEPUTY BOROUGH ELECTRICAL ENGINEER—The Borough Electrical Engineer, Electricity Showrooms and Offices, 197–199 Chiswick High Road, London, W.4 (December 11).

ASSISTANT (full-time) to teach ENGINEERING Subjects in the Stockton-on-Tees Technical School and Evening Institute—The Director of Education, Shire Hall, Durham (December 11).

ASSISTANT LECTURER IN PHARMACEUTICAL CHEMISTRY in the Chemistry Department, and a LABORATORY STEWARD IN THE DEPARTMENT OF ZOOLOGY—The Registrar, University College, Nottingham (December 11).

SIBTHORPIAN PROFESSORSHIP OF RURAL ECONOMY—The Registrar, University Registry, Oxford (February 24).

LECTURER IN GEOGRAPHY—The Secretary, The University, Aberdeen (March 31).

ASSISTANT IN THE BOROUGH ANALYST'S DEPARTMENT—The Town Clerk, Town Hall, Burnley, Lancs. (endorsed "Assistant, Analyst's Department").

LECTURER IN THE APPLIED CHEMISTRY DEPARTMENT—The Secretary, Northampton Polytechnic, St. John Street, London, E.C.1.

TEACHER (experienced and well qualified) OF MATHEMATICS AND SCIENCE—The Principal, Technical Institute, Darnley Road, Gravesend.

DEPUTY LIBRARIAN in scientific library—The Secretary, Geological Society of London, Burlington House, Piccadilly, London, W.1.

HEAD OF THE BOTANICAL ECOLOGICAL SECTION—The Secretary, Scottish Seaweed Research Association, Ltd., 28 Rutland Street, Edinburgh 1.

PHYSICAL CHEMIST, a BIOCHEMIST, and two TECHNICAL ASSISTANTS—The Director, Cereals Research Station, Old London Road, St. Albans.

## REPORTS and other PUBLICATIONS

(*not included in the monthly Books Supplement*)

### Great Britain and Ireland

Transactions of the Royal Society of Edinburgh. Vol. 61, Part 1, No. 8: The Petrography of the Franz Josef Fjord Region, North-East Greenland, in relation to its Structure; a Study in Regional Metamorphism. By Dr. N. E. Odell. Pp. 221–246+4 plates. 8*s.* 6*d.* Vol. 61, Part 1, No. 9: The Cephalopoda of Scottish and Adjacent Waters. By Dr. A. C. Stephen. Pp. 247–270. 6*s.* (Edinburgh and London: Oliver and Boyd.) [1210

Post-War Forestry. A Report on Forest Policy prepared by the Royal Scottish Forestry Society and the Royal English Forestry Society. Pp. 62. (Edinburgh: Royal Scottish Forestry Society; London: Royal English Forestry Society.) [1710

## PROFESSIONAL INSTITUTIONS

IN an important passage in its statement on "Scientific Industrial Research", Nuffield College directs attention to a problem arising out of the use of university laboratories or research workers for applied research. The suggestion is made that if there were a code of conduct recognized as generally applicable to university scientific workers undertaking outside industrial work for private firms, it would be a comparatively easy matter to work out a special code to cover these problems so as to avoid alike restrictive conditions, on either side, slackening in the pursuit of science, or undue influence over university departments by particular firms or industries. Obviously, as the memorandum indicates, the entire problem is one to be tackled jointly by the universities, professional associations and industrialists, and it is one in which the initiative might be expected to come from the professional associations of scientific workers themselves.

This is a particular example of the kind of contribution which Prof. Carr-Saunders and P. A. Wilson visualized professional associations making to the development and welfare of society in their study some twelve years ago of the professions. It is of more interest since there have in the interval been so few signs that professional associations are aware of the immense opportunities before them in this connexion, or how great could be their contribution to the reconstruction of the crumbling or broken fabric of democratic life. Without their advice and co-operation, the right atmosphere and the appropriate conditions for fruitful research may be difficult to attain; and there are other fields in which the professional contribution may be equally invaluable. As Carr-Saunders and Wilson noted, it is not that professional men are innately reactionary or unprogressive, but that they lack vision. "They do not grasp the essential features of the social and economic structure and the place of the professions in it. Moreover in so far as they do interest themselves in matters outside the development of their own technique, they often fail lamentably to display the same standards of exactitude and judgment as they demand with vigour in their immediate spheres. The pity of it is that their opportunities are so great and that they have so large a part to play, if only they would open their eyes and summon up courage to act in the large issues of contemporary life."

Despite honourable exceptions, it cannot well be said that that criticism is any the less true than when it was written, nor has there been any notable progress in the study of the urgent problem of proper relations between professional associations, as repositories of specialized knowledge, and the democratic State. We cannot reasonably claim that, despite the enhanced importance of planning, much obvious thought has been given to the problem of the methods which professional associations should employ to present their views and which the State should use to obtain their advice. The organization outlined early this year in the White Paper on Scientific Research and Development has grown almost

haphazard, but it at least meets the essential criteria of Carr-Saunders and Wilson that there should be many channels of communication between knowledge and power, that they should be kept wide open, that proposals and criticisms should be freely circulated and that the mechanism should be flexible and capable of easy adaptation as circumstances demand.

That organization, however, scarcely provides for adequate consultation or representation of professional associations, whose representations are sometimes more effectively made through the Parliamentary and Scientific Committee. Its emphasis is rather on the individual expert than on his professional association, and therein lies a great weakness. One function of the professions as such is to bring knowledge to the service of power but, as Carr-Saunders and Wilson point out, that function is, and can only be, effectively discharged when men and women, finding in vocational associations their permanent anchorage and shelter, set out from these secure positions to shape organizations into instruments for the fulfilment of their social and economic purposes. Unless that is done, the organizations set up to enable men and women to perform their special service in the ordinary business of life escape from control and become a menace both to professional efficiency and to social progress and well-being.

That contribution is the more important if we consider, as Prof. H. J. Laski argues in his "Reflections on the Revolution of our Time", that the present fleeting opportunity of revolution by consent, and of experimenting with the conditions which make possible the resumption of expanding welfare, involves putting the idea of freedom in the context of equality, and discovering exactly how freedom and democracy interpenetrate one another. Post-war reconstruction and the fundamental adjustment of society to the changes in structure which the War has already brought about, offer a great and inescapable challenge to professional organization and thought. If professional men do not face the problem of reconciling freedom with power and responsibility, the prospects of winning the peace are indeed dark. To put professional advantage in face of public duty at the present time would be, in the end, fatal to their own interests. Collectively and individually, scientific workers can no longer live in their laboratories or professional associations as ivory towers: they are concerned with the social context of their work, and to see that social and political policy do not frustrate the quality or extent of their contributions to social well-being.

The chapter "Freedom in a Planned Democracy" in this same volume deserves close attention for its stimulating suggestions of the kind of contribution which trade unions and other professional associations might make in a new social order in which the concept and context of freedom are positive rather than negative. It is, in fact, this negative concept that has warped the activities of the trade associations and fostered restrictive practices, as it does in the professional field. In a new prospective in which that fear of want and insecurity is removed, professional associations will find their protective functions far less important than the contribution they can make to the improvement of the standards of professional practice, in science, in law, in medicine and in technology. Trade unions in such a context might well be set free from present inhibitions and take a fuller interest in the organization of industries in the interest of the community generally, the fostering of technical development and the support of scientific research.

These possibilities are at present scarcely glimpsed. The routines by which, as Prof. Laski rightly notes, men live have too often limited their professional horizon, and in an age of insecurity the threat to that routine has clouded their judgment. Again, arguing that the maintenance of democracy as a framework for the State is essential for the maintenance of free discussion and the spirit which scientific discovery requires, Prof. Laski maintains that a civilization at once so complex and so fragile as ours must postulate the need for scientific discovery as a primary condition of its survival. That effort, with all it means in scientific and industrial research, will demand, as we have so often urged in these columns, the widespread support and understanding of all sections of the community, and the importance of the contribution which the trade unions might make, given once a new outlook, is not easily overstressed.

The nature of the contribution of professional organizations to the social and economic structure has been further indicated by J. T. MacCurdy in a suggestive chapter in his little book "The Structure of Morale". One of the central problems of democracy is that of establishing a right balance between efficiency and liberty, and of providing effective means for discussion at the lower as well as at the higher levels. That is the importance of the production committees which the War has called into being; they may have a vital part to play in the fuller integration of industry with the community which its prime function is to serve.

The development of group loyalties in this way is of importance for two reasons. First, it encourages the expression of the ideals and experience of the individual, particularly of his creative powers, as Dubreuil has emphasized in his exposition of the idea of autonomous groups in industry. Secondly, it facilitates that contact between the upper levels of the hierarchical organization required for large-scale planning and the accurate and detailed knowledge based on experience at the lower levels which is essential for flexibility and the modification of policy in the light of experience. Huge organizations, as MacCurdy notes, are necessarily inefficient owing to their rigidity and inadaptability; to fabricate a social organization that is really adaptable, we have first to develop a liaison system comparable in its intricacy with the individual human brain.

Some recognition of this is to be found in such reports as that of the Social and Industrial Commission of the Church Assembly on "The Church and the Planning of Britain"; but it is unfortunately true that professional organizations, like the trade unions themselves, which might be making an invaluable

contribution to the development of a liaison or intelligence system of the type required, are specially liable to this disease of ossification, rigidity and conservatism to which all large-scale organization seems to be a prey. A number of professional associations have, it is true, recognized their responsibilities in regard to reconstruction, either generally or in some special field. It was a major purpose, for example, of the Institution of Professional Civil Servants in submitting its proposals for the reconstruction of the technical Civil Service (see p. 743 of this issue of *Nature*) that the professional and technical services should thereby be better equipped to give the more positive services to the community that will be required of them. The Association of Scientific Workers has issued two admirable statements on "Science and the Universities" and "A Post-War Policy for Science". The Institution of Electrical Engineers has established a Post-War Planning Committee to study post-war developments in electrical engineering, with terms of reference which imply not merely important contributions to public policy but also consideration of desirable changes in the structure and machinery of the Institution.

Special contributions in the particular fields where they are qualified have been made by such bodies as the Association of Architects, Surveyors and Technical Assistants and, through its Reconstruction Committee and Architectural Science Group, the Royal Institute of British Architects. In this connexion the Modern Architectural Research Group and the Engineers' Study Group on Economics should also be mentioned. None the less, the essential danger remains. It can be seen in the general outlook of considerable bodies of scientific workers, and it has to be taken into account in considering any such proposals as those of the Royal Statistical Society for a supplementary charter enabling it to institute a professional diploma for statisticians with the view of raising their status. The rational approach is seen in Dr. Frans Verdoorn's address in the symposium on "Biologists and Rehabilitation" arranged by the Botanical Society of America and the American Association for the Advancement of Science at Cleveland on September 13 (see *Nature*, **154**, 595, 1944). Such an impartial and fundamental approach to questions of scientific co-operation, whether national or international, and especially in such matters as publications, is all too rare.

What is required is, in fact, exactly such a reconsideration of the position and functions of professional bodies in relation to society against the background we have indicated, and with particular references to the inherent weaknesses of all such associations. This outlook is hard to find in the only recent survey of professional associations in the scientific field—a brief memorandum "The A. Sc. W. and Other Bodies", issued by the Association of Scientific Workers. Here once again the approach is subjective and functional; but the memorandum clearly indicates the need for rationalization, which some of the large bodies of scientific workers, such as the chemists, have refused to face. The memorandum may well serve as a starting point for further discussion of the whole subject. In particular, it may help to clarify some of the confusion in the public mind between the scientific or learned societies and the professional associations of scientific workers.

Broadly speaking, the professional associations with which scientific workers are concerned fall into three types according to their function. There are, first, the learned societies, concerned principally with the encouragement, discussion and publication of scientific research in particular fields. Headed by the Royal Society, they cover almost every subject, and it will be noted they are the oldest societies of scientific workers in existence.

The formation of these learned societies was followed at varying intervals by the establishment of organizations or institutes concerned with the maintenance of professional standards, first of qualifications and then of conduct or ethics. Some of them, like the Institution of Electrical Engineers, the Institution of Mechanical Engineers, the Institution of Civil Engineers, the Royal Institute of Chemistry and the Institute of Physics are chartered bodies and cover wide fields of pure or applied science. Other more recently established bodies such as the Textile Institute, the Institution of the Rubber Industry and Institution of the Plastics Industry are concerned with much more limited fields, and in activities, such as publications, overlap with the functions of the scientific societies.

The third and most recent type of professional association is what may be termed the defence organization concerned with the protection of the economic interests of qualified professional men, of which type the Association of Scientific Workers and the British Association of Chemists are the best known. Here again there is some overlapping, for so far as public analysts are concerned the Royal Institute of Chemistry has proved an effective defence organization and indeed was largely formed originally to promote the interests of the public analyst. Moreover, associations formed primarily for defence purposes have taken no narrow view of their functions and have often been as concerned to maintain standards of professional qualification as to protect the economic or professional interests of their members.

Apart from the confusion of functions, one of the weaknesses of the professional organization of scientific workers has been imperfect representation. Even some comparatively numerous bodies such as the Royal Institute of Chemistry with 9,000 members are not fully representative: there are, for example, some 20,000 names on the Chemical Section of the Central Register. Others, even when fully representative of the profession or technique, are numerically too weak, and efforts to redress numerical weakness by merging with other bodies or by lowering the standard of qualification are obviously detrimental alike to public and professional interest. For the chartered institutes to fulfil their primary functions it is imperative that they maintain uniform recognized levels of qualification, on the basis of which the profession can become a well-defined and coherent whole. These levels of qualifications must be recognized and

observed by the corresponding defence associations also: whatever measures are required to safeguard the interests of laboratory assistants, they emphatically should not include admission to the associations of fully qualified practitioners, however important it is that such associations should be closely concerned with the welfare and training of potential candidates. The Association of Scientific Workers shows a complete misconception on this point where its memorandum suggests that a grade of membership of the Royal Institute of Chemistry is required to cover the partly qualified assistant chemist or laboratory assistant.

Some rationalization of professional associations and societies is clearly desirable, particularly in regard to their practice in publication; but each of these three functions has its own contribution to make in bridging the gap between knowledge and power and furthering that intelligence system so essential in an effective democratic society. Moreover, the development of more effective organization for corporate representations, such as the Joint Council of Professional Scientists set up in 1942, may in time encourage such rationalization and the more effective use of available resources in publications and other matters. Again, the experience of some of the smaller societies such as the Oil and Colour Chemists' Association and the Society of Dyers and Colourists, particularly with their technical advisory panels, in assisting Government Departments in solving war problems, is of importance as indicating services which might be less easily rendered in a larger organization.

Rationalization of the associations of scientific and other professional workers can only be looked for when the point of view expressed so admirably by Carr-Saunders and Wilson permeates their councils and governing bodies and the members generally. When that time arrives, we may hope for a thorough and impartial scientific examination of the whole problem, and the outline of a plan unwarped by deference to the embedded prejudices or traditions to be found vested among scientific organizations as elsewhere. The report of the British Commonwealth Science Committee contained some concrete proposals on these matters to which there has been as yet little evidence of any general response. Meanwhile, the consciousness that effective post-war planning can only proceed as the appropriate means are found for science to make its contribution at the right stage may give a fresh impetus to the consideration of the organization of our scientific effort and the development of improved liaison between the Government and professional associations. Again, the acute difficulties in which scientific publications in Britain are now placed, partly as a result of the paper position, may induce fresh efforts to deal with the publication of scientific research and its exposition to industry and the general public on a more rational basis, and also with the vexed and difficult question of the abstracting of scientific and technical literature. Dr. Verdoon's suggestions on this point in regard to biological literature have a wider application and deserve note by scientific workers generally. The experience of the Joint Council of Professional Scientists may assist the development of new means of collaboration, but something more than organization will still be required. Without some wider vision and more urgent sense of professional responsibilities and of the possibilities and opportunities of public service, we cannot expect scientific workers and other professional men to take the first and most difficult step involved in scrutinizing anew their professional organizations in the light of the needs of the day and the fundamental principles and purposes they have to serve. Adequate organization is essential, but even more important is a high sense of public duty and the willingness to co-operate for constructive purposes. It is only when the threefold functions of professional associations are pursued co-operatively and in balance, and not to the nurturing of one at the expense of others, that professional men will play the essential part that is theirs in extending the empire of reason over the minds and habits of men, and replacing arbitrary discretion in any man or group of men by settled and agreed principles within the ambit of which their conduct must be controlled. On these two things, both fundamentally denied by Nazism and Fascism, civilization depends.

## GEOLOGY WITHOUT TEARS

**Principles of Physical Geology**

By Prof. Arthur Holmes. Pp. xii+532+95 plates. (London and Edinburgh: Thomas Nelson and Sons, Ltd., 1944.) 30*s*. net.

A GEOLOGICAL author who introduces the word 'Principles' into the title of his work is wittingly inviting a comparison with Charles Lyell's masterpiece, "The Principles of Geology", which, more than a century ago, laid the foundations of the modern science. Whereas Lyell's was a work of genius, the present book is not; but this is no matter for the slightest regret. It may be debated whether geological science at this present time needs a genius or could make much of one were he to appear, but there can be no question at all that it needs an expositor—and here is one with a rare combination of lucidity and sprightliness. Geologists have wailed of late about the neglect of their science and of themselves in many fields both warlike and peaceful, and have traced this neglect to the ignorance of geology among all classes of the community in Great Britain and especially among those classes which should know better. Their laments have certainly been justified, but they have proposed few workable remedies. It seems that the cure has lain all the time in the hands of the geologists themselves; they cannot expect many people nowadays to struggle for knowledge, and they must accordingly make their wares attractive and take them to the customers. Here is a very attractive article indeed.

To begin with, the story of the development of the surface of the earth should interest everyone outside a penitentiary cell or a similarly secluded luxury flat, for the simple reason that we walk about on that surface, grow our food in it, get the raw materials of industry from under it and, in these days of so-called progress, dig a nice safe shelter deep below it. Apart from this, the story itself is exciting, with revolutions every so often, with the ceaseless interplay of varied

forces, with a little happening for a very long time and a lot happening in practically no time at all. As has been said already, Prof. Holmes displays these matters with complete clarity, and in an even and fluent style. Further, at this time of 'economy standards', it is sheer delight to read and handle a book printed in pre-war fashion on a white paper in a good type and with wide margins, and furnished with an abundance of excellent illustrations in plates and figures. There seems to be no reason why this book should not be a best-seller, and with much more justification than most.

The book is divided into three parts. The first, and least satisfactory, is an introduction to geology intended to equip the reader for a proper appreciation of the following two parts. To write a short account of the fundamentals of a science is a far more difficult job than to write a long account of its latest developments; by the same token, the ablest teachers should teach the elements of their science and leave the last graduate to retail competently the embellishments of his own times. This first part, and a very fundamental part it is, appears to have been insufficiently thought out. It seems unlikely to the reviewer that an ordinary intelligent non-geologist could make much of certain sections of it.

Parts 2 and 3, on the other hand, are excellent. The first of these deals with operations at the surface and gives an account of weathering and the sculpture of the lands by water, wind and ice. This part ends with modern statements on life as a rock-builder and as a fuel-maker, that is, on the rocks of organic origin, limestones and coals and petroleum. It may be remarked here that the author tends to suggest that all problems in geomorphology and surface activities generally have been solved; fortunately, this is by no means the case.

In the last section of the book, we get below the surface and are presented with an exciting account of internal processes and their results. Earthquakes and volcanic activity are dealt with in a competent, modern manner. The two styles of earth-movements, the orogenic or mountain-building and the epeirogenic or plateau-building, are described, the illustrative examples being so chosen that not only is the tectonic make-up of the continental masses summarized but also more detailed expositions of specially interesting units such as the African rifts, for example, are presented. The last chapter discusses the theory of continental drift. This section differs in tone from the previous one, in that it is now admitted that there are a great many problems still unsolved; but Prof. Holmes appears to suggest that solutions for most of these will eventually be found along the lines proposed by him. Thus, the notion of internal convection currents, elaborated by the author in recent years, is applied to account for mountain-building and for volcanic activity, and is used as the mechanism for continental drift. It is, of course, right and proper for a geologist or anyone else to have a profound belief in his own proposals, but this is no guarantee that the belief will be widely held by others. It would have been better and fairer for the general reader if some of the many other speculations on these topics had been mentioned, if not discussed.

In the estimation of a book of this calibre, minor criticisms—and many could be made—would verge on the pettifogging. There is one regrettable lapse that must be excised in a new printing; that fine Dartmoor tor at Manaton is disgraced by the title of the Mussolini Rock! In spite of minor defects that could easily be remedied, the book rises well above any recent work in English in its own field. It is to be hoped that the geological education of the community begun by this book will be continued in as pleasant a manner. H. H. READ.

## POPULATION GROWTH

### Plenty of People

By Warren S. Thompson. (Science for War and Peace Series.) Pp. x+246. (Lancaster, Pa.: Jaques Cattell Press, 1944.) 2.50 dollars.

"THIS book is an attempt to introduce the lay reader to the problems of population growth", says the preface. The author outlines—no more—the major economic, social, and military problems arising from populations either too big or too small for the areas which they inhabit. The fifteen chapters (or rather fifteen essays in random order) cover a world survey of population growth, with useful statistical material on birth- and death-rates, and a discussion of the relationship between population growth and age-composition, war, migration, international trade, and the treatment of minorities. A section on eugenics blames family environment rather than heredity for producing delinquent offspring from delinquent stock. Finally, the author describes existing population policies, particularly Germany's, and suggests a policy for the United States.

Dr. Thompson's book is on purpose thinly documented out of too much care for the lay reader. The most disquieting gap is the lack of any reference to Fru Myrdals' "Nation and Family", which deals more profoundly with a section of the ground covered here. Dr. Thompson could also have improved his presentation by tabulating statistics where possible instead of writing most of them into the text, and by eliminating repetition. However, these criticisms should not overshadow Dr. Thompson's basic achievement; he simplifies difficult problems without omitting major arguments, and he underlines the main points by excellent graphs and diagrams.

Dr. Thompson distinguishes two distinct stages in the development of population control. First, control of the death-rate. Secondly, control of the birth-rate. The period of greatest population growth occurs when a community has learned to control its death-rate, but has its birth-rate still at maximum capacity. There is obvious correlation between such periods of population growth and industrialization. Here Dr. Thompson is wary. Pieced together, his view seems to be that increased industrialization, that is, productivity, provides resources which result in a reduced death-rate. The consequent population increase itself creates a need for further industrialization so that the standard of living can not only be maintained, but also raised to meet a whetted appetite. This circular argument accounts for apparent discrepancies, since different parts of the book intersect it at different places. The main point is, however, clear—the Western countries have in effect passed their periods of population expansion; but the features which characterized the nineteenth century in the United States and in Great Britain will in the near future characterize eastern Europe and, particularly, Asia. "They are learning how to control their death rates and to use machines." Japan, India,

China and the Soviet Union will soon rival the West, which will "cease to have sole possession of the economic and political advantages of an efficient machine industry and a rapidly growing population". In the author's opinion this will lead to wars of rivalry unless the Western nations will relax their hold on raw material resources and on under-populated areas. The Netherlands East Indies, and British Borneo and New Guinea could, he says, absorb immigrants, so could Canada and South America. But he is harshest on Australia, declaring that so long as she wilfully keeps her population some sixteen millions below potential capacity, other nations should refuse to meet her resultant military need.

The second stage in population control comes when communities learn also to control their birth-rate. At first this control operates less effectively than control of the death-rate. A rapidly declining death-rate is coupled with a slowly declining birth-rate, so that the population grows. Then the birth-rate falls faster, while the death-rate probably becomes fairly stable, health measures having reached near-maximum efficiency. At this stage nations can be said to have *control* of population growth, but this does not imply, of course, that they have any population *policy*. However, nations with a conscious policy can put it into effect only when they have achieved control of birth- and death-rates. Control of the death-rate is not a flexible instrument. Control of the birth-rate could be, and it is here that policy must operate. Each nation must itself decide whether to aim at replacement, or at more or less than replacement. Its propaganda and its social values and inducements must be set accordingly. Until such a policy is decided and made known, each family will make its own private decision about the size of its family, possibly with disastrous effects on the general well-being.

The population policies of each nation should, says Dr. Thompson, "concern themselves with the adjustment of population to its resources, giving consideration to the manner of life it considers good". This definition is not valid, however, as long as population is uncontrolled in other parts of the world. The Malthusian situation arising there will almost certainly provoke wars. Dr. Thompson is explicit about this; if all mankind is to have a decent standard of living, and, as a consequence, to live at peace, the birth-rate should nowhere exceed one third of the physiological maximum. This dictum assumes a policy for peace, but militaristic nations, or those in dread of militaristic neighbours, will scarcely favour a reduced population. Population policy may then become the opposite of that calculated to promote the welfare of citizens considered primarily as human beings.

Apart from military considerations, Dr. Thompson sees no harm in a declining population for Great Britain, Italy or Germany, and advocates it strongly for China, India and Japan. But Australia, New Zealand and Brazil should expand, he thinks, and the United States stabilize at around the predicted 1975 level. The optimum birth-rate is different for different countries and at different times. The outstanding contribution of Dr. Thompson's book is this insistence that national population policies are practicable and essential, but that these cannot be settled in isolation. Relative population numbers should, if this thesis be accepted, become a subject for future international agreement.

# DE GENERATIONE

## Aristotle. Generation of Animals

With an English translation by Dr. A. L. Peck. (Loeb Classical Library.) Pp. lxxviii+608. (London: William Heinemann, Ltd.; Cambridge, Mass.: Harvard University Press, 1943.) 10*s*. net.

ARISTOTLE'S biological works have never lacked translators and commentators. The latter found in them ample scope for their learning, and particularly for their ingenuity, in so far as the texts, in the words of the late Prof. A. Platt, "have suffered terribly in the process of transmission to us, and are full of grievous blunders committed by scribes". The first complete English translations by Thomas Taylor, published in 1807–09–10, were printed in so small an edition that they are among the rarest of books. The translations available to the modern English student are: "History of Animals" (Cresswell, 1862) and D'Arcy Thompson (1910); "Parts of Animals" (Ogle, 1882, 1912 and Peck, 1937); "Generation of Animals" (Platt, 1910) and the present work by Peck (1943). The last-named author is at present working on another translation of the "History of Animals", which will complete the trilogy of Aristotle's biological works in the Loeb series. Dr. Lones' general survey of these works (1912) serves as an admirable introduction to their range and importance. That ancient and curious volume known as "Aristotle's Compleat Master-piece", first published in 1684, which was already in its thirty-second edition in 1782, is still in print, despite its fallacious title and useless contents.

Translations of Aristotle's biological works have as their main concern not questions of linguistics but of subject-matter, or in other words they appeal not so much to the Aristotelian scholar as to the biologist. Nevertheless, the perfect translation must be able to satisfy both the Grecian and the man of science. This would seem to require the collaboration of two workers, since it rarely happens that the diverse interests of language and science come to rest in one individual, as they do so happily in the majestic personality of Sir D'Arcy Thompson.

Dr. Peck's approach to his task is that of the classical scholar; but he realizes that Aristotle in this work on generation is an original thinker as well as a descriptive embryologist. Indeed, as Dr. Peck himself points out, Aristotle compiled the first systematic treatise on animal generation, in which he may be said to have: (1) founded comparative embryology; (2) favoured epigenesis as opposed to preformation; (3) initiated the study of organogenesis; (4) deduced the functions of the placenta.

In addition to the obvious advantage of printing the original Greek text and the translation on opposite pages, Dr. Peck gives us a carefully revised version of the former, and also a valuable exposition of Aristotle's thought, methods and technical terms. Further, there are a useful summary and a detailed index. Such defects as there are in this edition are of quite minor interest. For example (p. xix), it is not correct to say that "Harvey was indeed the first to make any substantial advance in embryology since Aristotle". Nor must we forget that Highmore, simultaneously with Harvey, demonstrated the real nature of the cicatricula of the fowl's egg. On page 205 Dr. Peck says that Aristotle's kestreus "cannot be the grey mullet, but is probably a species of *Muraena* or *Gymnotus*". The latter genus is confined to the

New World, and Linnæus's eastern species of '*Gymnotus*' could scarcely have been known to Aristotle. On the other hand, the mullet attribution is confirmed by Aristotle's statement that his kestreus had a gizzard-like stomach, which *Muraena* certainly has not. Page 302 *f*., Aristotle's placental fish was rediscovered by Steno in 1673 before J. Müller. Page 390, footnote *g*, includes a misprint which is good Scots, but not what Dr. Peck meant to say. But slips like these do not detract from the essential importance of the work, even if it is not ungracious to mention them, and all students of the history of biology will be deeply grateful to the author for an outstanding addition to Aristotelian literature. F. J. COLE.

# INORGANIC CHEMISTRY OF NITROGEN, PHOSPHORUS, OXYGEN AND SULPHUR

## Systematic Inorganic Chemistry of the Fifth- and Sixth-Group Nonmetallic Elements

By Prof. Don M. Yost and Horace Russell, Jr. (Prentice-Hall Chemistry Series.) Pp. xx+423. (New York: Prentice-Hall, Inc., 1944.) 6 dollars.

BY selecting a rather small but highly interesting and important part of the chemistry of the elements, the authors have been able to give, in a short compass, a very valuable survey of topics which should be of the highest value to students and teachers, and also, since adequate references to literature are given, to those seeking further information on the subjects with which it deals. Particular emphasis is laid on such modern aspects as molecular dimensions and shapes, and bond-lengths, and there are usually rather full statements of all the quantitative properties of the substances dealt with.

It is clear that the authors have made very full use of the original literature, and have provided concise yet highly informative summaries of a large number of papers. As an example, the fifteen-page account of the metaphosphates may be mentioned, this including all the results of a large amount of difficult literature in a clear, ample and readable form. The treatment is critical without being obtrusively so. There are many good graphs of properties and diagrams of molecular structures; but the book as a whole is rather weak on preparative chemistry, and the reviewer missed diagrams of apparatus even in cases, such as the description of the preparation of hydrogen persulphides, where these are essential in appreciating the methods.

Some matter which could well be omitted from such a book, such as the half-page dealing with the theory of electron gas on p. 141, would, in the reviewer's opinion, better have been replaced by preparative detail, but this is perhaps a point on which opinions will differ. In the description of the glow of phosphorus (p. 170) sufficient emphasis is not given to the work of Miller, quoted on p. 177; this section should be revised in a new edition. The reviewer noticed very few misprints; "Bayley" instead of Baly on p. 4, and $H_2PO_3$ instead of $H_3PO_3$ in the heading on p. 198, are examples of what can be put right in a later edition, and the text seems remarkably accurate. The book is very well written, the interest being maintained even in sections containing mostly numerical data, and students should find it stimulating and arousing interest in the subject. It is permeated by what one may call the 'research spirit', and the authors say in the preface that it contains much information from their own experience.

The fifth and sixth groups of the Periodic Table contain some of the most interesting elements, and this applies also to the metals, which the authors, unfortunately, have not been able to include in the book.

Whether for its well-conceived and executed plan, or for its objective tone, the book deserves very high praise indeed, and will undoubtedly take its place in the list of books every chemist will wish to possess. The printing, paper and binding are worthy of the text.

# THE RELATION OF BODY AND MIND

## Food for Thought

A Treatise on Memory, Dreams and Hallucinations. By Bernard J. Duffy. Pp. 160. (London, New York and Toronto: Longmans, Green and Co., Ltd.; Dublin: Abbey Publishers, 1944.) 10*s*. 6*d*. net.

THE evidence in favour of telepathic communication (supra-normal cognition or extra-sensory perception) is now enough, and more than enough, to convince any reasonable inquirer, and it may be time to consider theories to explain how it happens. A theory of physical transmission from agent to recipient, that is capable of experimental test by ordinary methods of scientific investigation, is to be preferred if it is at all possible, to any theory that cannot be tested in this way. Indeed, for those who hold that everything must have a physical explanation, such a theory is urgently needed.

Mr. Duffy puts forward a hypothesis of the relation of body and mind that belongs to the same genus as that of Descartes; namely, that mental processes are activities of a spiritual substance distinct from the bodily organism, but interacting with it through a specific physical mechanism. The mechanism Mr. Duffy suggests is that active brain cells produce weak radiation of wave-lengths about the range of the shortest used for radio transmission. Normally, each mind interacts with its own brain, but exceptionally with another; hence telepathy. The evidence quoted for the existence of such radiation is not convincing, but it seems a possibility, and it is almost certainly the last hope of a physical explanation of telepathy. There seems to be no reason why chemical reactions in nerve cells should not produce weak rays of wave-length between a metre and a micron; why radiation from a group of cells should not form a beam; why it should not be projected to great distances. On this hypothesis, telepathic reception should be highly localized; agent and recipient could be screened from one another; artificial production of rays of appropriate wave-length should have striking results. All these suppositions can be tested.

There are serious objections to any type of Cartesian theory of the body-mind relation, which even Mr. Duffy's ingenious suggestions do not overcome. There are considerable objections to any radiation theory of telepathic transmission. Still, an improbable theory which can be tested has a scientific value so long as it has not been disproved, and no theory in this sphere starts with any high probability. Mr. Duffy's theory, therefore, deserves serious consideration. A. D. RITCHIE.

# INTERNATIONAL ACTIVITIES IN SCIENCE*

By SIR HENRY DALE, O.M., G.B.E., P.R.S.

WITH the outcome of the War ever more certain, there can be no relaxation yet of the demand on what our scientific effort can contribute to the hastening of its end. It is none the less our duty to begin to look further ahead and to prepare for the part which science must play in the world which will follow. The needs of alliance in war have evoked, especially between the two great branches of the English-speaking nations, a closer interchange and collaboration in science, between men of different national traditions and loyalties, than has ever before been a matter of organized policy. It is not too early to begin to consider to what degree, and in what form, such a collaborative effort should be continued into the conditions of peace, and extended to scientific men of international goodwill throughout the world. Even in the twenty years of uneasy armistice which ended in 1939, a measure of co-operation among the world's scientific men was achieved.

Our traditions go back to days when the fellows of the Royal Society belonged to a community embracing all Europe in its enthusiasm for the new experimental philosophy, and the Society will have a particular duty to be among the leaders in the resumption of international activities in science, and to use all its influence to establish these on an ever wider and firmer basis. The Society has a standing committee on international relations in science, with its foreign secretary appropriately as chairman, to prepare for what action the Society can usefully undertake or promote, as the opportunity presents itself. Meanwhile, we may observe other signs that the spirit of international friendship and recognition in science is beginning to move again, even while the chaos of war is still with us. Among such signs, we may note that one of the committees which, since their foundation in Stockholm, have awarded the Nobel Prizes with unchallenged impartiality among the scientific discoverers of all nations, has resumed awards this year. The Royal Society has welcomed the return to London of a group of distinguished French leaders in science from the United States of America, whither they had escaped from the hostile occupation of their country. We have been able to share their rejoicing at the liberation of France, and to welcome here others who had remained there, often in hiding and always in peril, as leaders in the steadfast resistance opposed by all but a negligible minority of the French men of science to the enemy's demands for their collaboration. Even to-day we are able to welcome another distinguished French colleague, just arrived from Paris —Prof. Emil Borel. We are glad to think that new and lasting bonds of comradeship in science have been created for us with those from other allied countries occupied by the enemy who have been our country's war-time guests, and through them with all the men of science in the countries which they represent. A happy chance brings also to our meeting to-day four men of science from the U.S.S.R. Very near to the heart of every British man of science is the desire for a growing intimacy of confidence and collaboration with our colleagues of that great partner-nation in the war for the world's freedom.

The Royal Society had recently the opportunity of showing its interest in the revival of international scientific co-operation in another special connexion. During October 16–19, a small international conference met in the Society's rooms, under the auspices of the Health Organisation of the League of Nations, to discuss the creation of an international standard of reference for penicillin and the definition, in terms of this, of a unit of activity.

Though the League has failed tragically of its central purpose, it has achievements of value to its credit, and science has an interest in ensuring the permanence of some of these. I have myself had the privilege of taking part in the activities of an international commission under the Health Organisation of the League, which succeeded, in the years between the Wars, in obtaining world-wide acceptance of standards and units of activity for a whole range of modern remedies—antitoxins, hormones, vitamins and certain drugs—the strength of which could only be determined by direct biological measurements of the specific activity, in comparison with that of a fixed standard preparation in each case. Insulin was an early instance of a new remedy requiring such intervention; its general use for the treatment of diabetes could not have attained the present level of safety and effectiveness, unless a world-wide uniformity on these lines had replaced the chaos of widely different units in different countries, which was threatened in 1923. Now research has produced another new remedy, penicillin, the success of which, in the treatment of a range of dangerous infections, has also had such a dramatic quality that its reputation has spread rapidly beyond our scientific community and caught the interest even of a war-distracted world. Here, indeed, was a discovery which could rank as a major contribution of science to the mitigation of the suffering which war inflicts, and, at the same time and no less, as a gift of healing to mankind at peace. The needs of war had given a stimulus to the researches which proved penicillin's remedial value, but its rapid production on an adequate scale had to face greater difficulties in Great Britain, where material and human resources had been more completely absorbed by earlier requisitions than in the United States. So the present position was reached, in which, as we are proud to recognize, the existence of penicillin and then, after a decade, the methods by which it could be separated in sufficient purity to demonstrate its brilliant possibilities as a remedy, were discoveries made here in England, while, in the further researches and technical developments needed for its large-scale production, our American colleagues have played a major part.

Thus early in its history, therefore, penicillin and its applications had become a matter of international concern; and, though war had restricted the work in this field almost entirely to scientific workers of the English-speaking peoples, and had brought them into an unusual intimacy of co-operation, progress had been so rapid and action so urgent that there was a real danger of a divergence of meaning in the terms used to express its activity and define its dosage, even among the few countries already using it. Prompt action was required to avert this by accepting a common standard of reference; and, when the proposal of a conference for this purpose was made from Great Britain to the League of Nations Health Organisation, we were grateful to our colleagues from the United

* From the address at the anniversary meeting on November 30.

States, as well as from Canada and Australia, for the generous promptitude with which they agreed to make the journey to England, so as to meet with us here in London. After all arrangements for the holding of the conference here had been completed, the liberation of Paris opened a new possibility; Dr. Tréfouel, now director of the Pasteur Institute in Paris, was able at the last moment to accept an invitation to join us, and thus to give our deliberations, and our eventual agreement, a wider international basis.

To illustrate how rapidly a divergence may arise under present conditions, I may just mention the fact that several different penicillins have now been recognized, produced by variations in the metabolism of the growth, possibly due to mutations of the mould itself, possibly to changes in the nutritive conditions offered to it by the medium or the cultural method employed. Three such varieties of penicillin have already been isolated in pure condition, and distinguished by certain chemical characters; but, while British workers had come to refer to these as penicillin 1, 2 and 3, their colleagues in America spoke of penicillin F, G, and X; and it was not until they met around the table at the Royal Society a few weeks ago, but then in less than ten minutes, that they became quite certain of the identity of 1 with F, of 2 with G, and of 3 with X. All these penicillins have the specific remedial action in high, though not quite identical degrees, and there are probably differences, still to be explored, in their proportional efficiencies against different infective organisms. When once their identities were thus put beyond doubt, however, the small conference had no hesitation in deciding, for the present, to use as the common basis of reference a sample of the penicillin which is predominant in most preparations now available, and most easily obtained as a pure salt in adequate quantities. The unit could then be defined as the activity of a precise, though very small weight—0·6 $\mu$gm.—of a particular sample of the perfectly dried, crystalline sodium salt of penicillin 2, or G; and the unit thus chosen for definite fixation, and for international recognition henceforward, was, by a unanimous choice, so defined as to be as closely equivalent as possible to the unit first propounded by Sir Howard Florey's team of collaborators, and widely known as the 'Oxford' unit.

The international standard for penicillin is thus added to an already numerous series, of which the custody, on behalf of the League of Nations Health Organisation, has been shared by the National Institute for Medical Research with the State Serum Institute of Denmark, at Copenhagen; and all these standards, we may hope, will be available for transfer to whatever international authority may be established in succession to the League, as a tangible and material result of genuinely international collaboration, which the League has been able to initiate and maintain among men of science, to the permanent advantage of the world.

Though penicillin has rightly made a special appeal to the imagination and sympathetic interest of a wide public, it is, of course, only one out of a varied range of inventions and discoveries, hastened by the stimulus of war's demands and produced, in many cases, behind the veil of its secrecy; but ready, when peace returns, to take their proper place as new gifts to the welfare and the civilized progress of mankind. From what has already been made generally known, it is clear that we may look forward to revolutionary advances in the means of communication and in the speed and safety of travel across the world and in methods of controlling insect pests and the diseases which insects convey. These are but a few examples of the gains which we and the world may hope to set against the tragic loss and sacrifice of the years of war.

There were probably few who even suspected in 1939 that science, in countries then so dangerously unready, would find itself, before the War ended, in its present position of central importance. None of us, I think, would claim more for science even now, than to have played in this War a part of growing predominance in the provision for the fighting men of the material means of warfare, without which their heroism and sacrifice could not have prevailed. Even that duty, loyally accepted, is one from which the scientific community of the free nations must long for the release which victory will bring. But, while the operations of war have come to depend on science to a degree beyond all earlier experience, it cannot be doubted that little more than a beginning has yet been made in exploiting the possibilities of destruction, which science could progressively offer, if the world should continue thus to misuse it, and if science were still on offer for such ends. Allow me to quote a passage from a letter which the Prime Minister, whom we are proud to number among the fellows of the Royal Society, wrote a year ago to Prof. A. V. Hill, in sending his greetings to Indian men of science.

"It is the great tragedy of our time," wrote Mr. Churchill, "that the fruits of science should by a monstrous perversion have been turned on so vast a scale to evil ends. But that is no fault of science. Science has given to this generation the means of unlimited disaster or of unlimited progress. When this War is won we shall have averted disaster. There will remain the greater task of directing knowledge lastingly towards the purposes of peace and human good." Noble words indeed, and a profession of faith which will find an immediate echo in the hope and the desire of every true man of science. "When this War is won we shall have averted disaster"—surely that is a confidence which every one of us will long to share. It must be clear, however, that Mr. Churchill's reference was to the present threat of disaster, from which the prospect of our escape is even more fully assured to-day than when he wrote, a year ago. We may be certain that nobody sees more clearly than he that the threat of final disaster to all man's hopes and achievements will not be for ever averted, if the possibility of the "monstrous perversion" of science is allowed to remain and to continue its evil growth. Even in the past year our enemies have thrown a new and vivid light on future possibilities, by the new weapons which science has enabled them to put on trial for our destruction. Though a people's unflinching courage and an answering effort of science and organization, together with the progress of the Allied Armies over the launching areas, have given us confidence that flying bombs and the like will not affect the issue of this War, the warning which they give, as to what the future might hold, is not the less clear. The writing on the wall must be plain for all to read. If, when the memories of the present War begin to fade, the world should allow science again to be exploited by a nation grasping at predominance by conquest, science will no longer be invoked only as an aid to what valour can achieve by land, sea or air, but as an agent, in itself, of blind annihilation at an ever-lengthening range.

When we men of science regain that freedom for the ultimate preservation of which we have loyally accepted, through these tragic years, the bonds of secrecy and submission to authority, we cannot put aside with these our proper share in the new responsibility for the future of mankind, which the experiences of this War have laid upon the men of goodwill in all nations. It is true, indeed, that neither the present abuse of science, nor any possibility of final disaster to civilization which might come of a future perversion of its powers, can be charged as a fault to science itself; no more, indeed, than we could properly charge to religion, as such, the wars which once devastated much of Europe in its name. But we men of science cannot escape from our growing share in the responsibility, in "the greater task", as Mr. Churchill has written, "of directing knowledge lastingly towards the purposes of peace and human good". No man of science has the right to prescribe for another his interpretation in detail of that duty; but there is one aim which may unite us, perhaps for the most effective action within our common grasp, and one which is worthy of all our common influence and effort. Let me quote again from Mr. Churchill's letter: "in this task", he writes, "the scientists of the world, united by the bond of a single purpose which overrides all bounds of race and language, can play a leading and inspiring part".

# ROYAL SOCIETY MEDAL AWARDS, 1944*

## Copley Medal

THE Copley Medal is awarded to Sir Geoffrey Ingram Taylor, Yarrow research professor of the Royal Society, in recognition of his contributions to knowledge of aerodynamics, of hydrodynamics and of the structure of metals, which have had a profound influence on the advance of physical science and of its practical applications.

Taylor is probably the most accomplished living exponent of the application of the methods of classical dynamics to problems of fluid motion. To great mathematical powers he adds high skill as an experimenter. His theoretical work is particularly noteworthy for its approach to reality. In place of the ideal conceptions presented by perfect incompressible fluids moving in stream-line motions and perfectly elastic solids, with which his great forerunners at Cambridge dealt, Taylor has studied turbulent motion, viscous and compressible fluids, and plastic movements of metals, obtaining results of great importance for the understanding of a wide range of phenomena.

Taylor's early work was concerned with eddy motion in the atmosphere, and opened up new fields of meteorological investigation. It threw light on the variation of wind with height and on the transference of heat and water vapour in the atmosphere, with a consequent bearing on the formation of fog. He also carried out work on the tides. Later he developed the theory of general turbulence, to which statistical methods can be applied which are somewhat reminiscent of the kinetic theory of gases.

Among Taylor's extensive researches on precise hydrodynamical problems, that on the motion of a viscous fluid between two coaxial cylinders, rotating with any speed in the same or in opposite directions, may be particularly mentioned, since it offers the only case so far of the complete solution of a problem of motional instability in the viscous liquid. In dealing with the elastic deformation of metals, Taylor has shown how the slip planes can be determined in certain cases by purely geometrical methods, and has offered a formal theory of the process of work-hardening in single crystals.

Taylor has also applied his great mathematical powers to a variety of practical questions. During the War of 1914–18 he did work of great distinction on aerodynamical problems for the Advisory Committee on Aeronautics, and during the present War he has been extensively concerned with complicated problems concerning the propagation of explosive processes. Taylor's work may be said to be in the line of a great British tradition, which, in the past generation, was represented by investigators like W. J. M. Rankine, Osborne Reynolds and Rayleigh. Like these he has the mathematical equipment, the originality and the insight required for the fundamental solution of problems presented by practical experience in the laboratory, in the workshop, and in the wider world. Taylor has carried his quest for experience and for scientific problems on to the sea and into the air. His work during this War has been of the greatest value to the nation and its allies, and his fundamental discoveries are extending the boundaries of knowledge for all mankind.

## Rumford Medal

The Rumford Medal is awarded to Dr. Harry Ralph Ricardo, consulting engineer, in recognition of his important researches on the internal combustion engine.

There is a special fitness at the present time in the award of this Medal to one who, during the last twenty years, has been the leading spirit in the development of the high-speed internal combustion engine. Ricardo's researches were begun under Bertram Hopkinson in 1905 and continued, after he left Cambridge, as a consulting engineer in his grandfather's firm. Investigating the effect of turbulence on the speed of combustion, he was led to appreciate the importance of 'knocking', to determine its cause and to show that the tendency to 'knock' is dependent on the nature of the fuel. Taking charge of a special design department for his firm, he produced a four-cycle, supercharged aero-engine, long in advance of accepted practice. In 1916 he was invited to plan a special engine for the secret fighting machine which was to become known as the tank, and his unorthodox and daring design was an outstanding success.

Forming a private company to maintain a laboratory for research on the internal combustion engine, Ricardo further investigated the relation of the phenomenon of 'knocking' to the maximum compression-ratio of the engine and to the character of the fuel, matching the latter by adding toluene in variable proportion to heptane, and thus paving the way for the modern octane-rating.

It is not possible here to make more than general reference to the far-reaching influence of Ricardo's investigations and his steady advocacy on the design of slide-valve engines, of sleeve-valve aero-engines, of high-speed Diesel engines, and on other important developments in engine design. In all directions there is evidence of his special genius and flair for design,

*Remarks made by Sir Henry Dale in presenting the Royal Society Medals for 1944.

and, behind this, of his full appreciation of the thermodynamical principles which control the behaviour of engines, and of a deep knowledge of the physical and chemical factors involved, as well as of the characters of fuels and of the materials of the working parts.

## Royal Medals

A Royal Medal is awarded to Prof. David Brunt, professor of meteorology in the Imperial College of Science and Technology, in recognition of his contributions to meteorology.

Brunt has made fundamental contributions to this science in its statistical, dynamical and physical aspects. The subjects which he has treated include cycles in weather; atmospheric radiation; atmospheric turbulence; the dynamical causes of rainfall; instability and convection in their bearing on the forms of clouds and on soaring flight; and the dynamics of depressions and anticyclones. He has rendered an outstanding service to his subject by his book on "Physical and Dynamical Meteorology", in which he gives the first connected and critical account of the physics and dynamics of the atmosphere, and reduces to order a large amount of material which was previously available only in isolated papers. The book contains much original matter, and has played a leading part in the recent development of meteorology in all countries.

Brunt has been a pioneer in the analytical approach to his subject. Of recent years he has devoted several papers to the discussion of the factors which influence bodily comfort, and has gone far to provide a natural basis for the classification of climates in relation to human health and human needs.

For many years Brunt has conducted, at the Imperial College of Science and Technology, a flourishing school of meteorology, which has attracted students from all parts of the world. He has always been generous with his services to colleagues in other fields who have required expert meteorological assistance. During the War his wide knowledge and sound judgment on meteorological questions have been of the utmost value to the cause of the nation and its allies.

A Royal Medal is awarded to Dr. Charles Robert Harington, director of the National Institute for Medical Research, in recognition of his work on the structure and synthesis of thyroxine, and on the chemical basis of immune reactions.

Harington's reputation, as a leader among biochemical investigators, was established by a brilliant series of researches dealing with the chemical nature, the origin, and the form of the natural combination of the thyroid hormone, thyroxine, with its remarkable content of iodine. He improved the method of isolating this active principle from the thyroid gland, determined its structural constitution and then produced it by artificial synthesis. Later he demonstrated that diiodotyrosine is present in the gland and accounts for the balance of its iodine content. By enzymatic cleavage he proceeded to show that thyroxine and diiodotyrosine are natural amino-acid constituents of the complex thyreoglobulin. These discoveries gave an entirely new precision to knowledge of the thyroid hormone, of the manner of its natural occurrence and function, and of the diseases which result from excess or defect of its supply from the gland.

In more recent years, Harington's work has contributed very important advances to knowledge of the chemical basis of immunological specificity. By a new method of coupling haptene groups artificially to proteins, he has studied the role of carbohydrates and of tyrosine in developing antigenic properties. By such methods he has created artificial antigens, the specificity of which is determined by the attachment of physiological active haptenes, such as thyroxine and acetylsalicylic acid. He has thus produced and determined the limits of specificity of antisera reacting with free thyroxine or acetylsalicylic acid, and has observed the antagonism of such sera to the physiological effects of such principles in the animal body. In other directions also Harington has made brilliant contributions to biochemical knowledge, as by his work on the conditions determining the crystallization of insulin and on the synthesis of glutathione.

## Davy Medal

The Davy Medal is awarded to Sir Robert Robertson, lately Government Chemist, in recognition of his researches on explosives, analytical methods, the internal structure of the diamond and infra-red absorption spectra.

After studying at St. Andrews, Robertson made his first acquaintance with the field of explosives as a chemist at the Waltham Abbey explosives factory, where he was occupied on the nitroglycerine plant. He acquired a knowledge of all aspects of the manufacture of cordite, and contributed improvements, such as the acetone recovery process which has been widely adopted. His researches in this period covered calorimetric measurements, and in particular the study of the mode of decomposition of gun cotton which led to the publication of work of great practical importance on the stabilization of that material (1916).

A succession of spontaneous explosions in cordite magazines led to a visit by Robertson to India and to the issue of an exhaustive and valuable report in February 1917. Shortly afterwards he entered the Research Department at Woolwich as superintending chemist, and he occupied this post with distinction until 1920. Much valuable work was done before and during the War of 1914–18. A process for the manufacture of T.N.T. introduced novel features and prepared the way for the large T.N.T. factories established under Lord Moulton. Other notable achievements by Robertson were the introduction of cordite R.D.B., which relieved the acetone position, and of amatol, of which it was said by the Director of Artillery that "amatol won the War". Throughout his time at the Woolwich Research Department, Robertson showed himself a resourceful investigator, an able leader and an indefatigable worker.

There followed for Robertson a further period of effective organization and active enterprise in research, as Government Chemist. He was one of the first to recognize the importance of infra-red spectrography for the determination of molecular structure, and in his pioneering work on the infra-red spectra of ammonia and of arsine he pushed the accuracy of the instruments then available to their ultimate limits. These researches directed the attention of chemists to the possibilities of the analysis of molecular vibrational and rotational bands, and materially assisted in opening up the wide field which has been explored in recent years. Robertson's studies of the absorption spectra of diamonds have produced

results of very great interest; they show that diamonds exist in two types differentiated by the condition of strain originating in their high-temperature formation.

During the present War Robertson has occupied very responsible positions in relation to the earlier field of his researches and has played a keen and active part in the contribution of chemistry to the national emergency.

### Darwin Medal

The Darwin Medal is awarded to Prof. John Stanley Gardiner, lately professor of zoology and comparative anatomy in the University of Cambridge, in recognition of his life's work on coral reefs.

Gardiner is universally recognized as an authority on coral reefs and on the organisms associated with such habitats. His contributions to these fields of biological and geographical research began not long after his graduation, when he was a member of the coral reef boring expedition to the atoll of Funafuti, organized by the Royal Society in 1896. Since then he has himself organized and led two most important expeditions, the first to the Maldive and Laccadive Archipelagoes in 1899 and the second to the Indian Ocean in 1905; the results of these expeditions are embodied in nine large quarto volumes and represent a most valuable contribution to a field of knowledge closely associated with the work of Charles Darwin. Within recent years Gardiner has organized and, to a large extent, directed the Cambridge Expedition to the Suez Canal, 1924; the Great Barrier Reef Expedition, 1928–31; the John Murray Expedition to the Indian Ocean, 1933–34; and the expedition to Lake Titicaca in Chile, 1937. He is an authority on the taxonomy and systematics of Alcyonarian and Zoantharian Corals, and has taken a keen interest in their ecology and geographical distribution.

Gardiner realized the great importance, in the study of corals, of the examination of the polyps themselves, as well as of their coralla, and he paid special attention to variations which may result from slight differences of habitat and are correlated with physical and other conditions, showing that in several instances so-called 'species' are merely variations. He also realized the immense value of an accurate knowledge of the coral fauna of any given locality in relation to its environment, in enabling one to deduce the conditions under which tertiary and earlier coralline deposits have been formed.

There is scarcely a branch of research on corals and coral reefs in which Gardiner's work is not of great importance. It was his observations on the Funafuti atoll and the atolls of the Maldive and Laccadive Archipelagoes that caused him to realize that no one theory, such as the 'subsidence' theory of Darwin, or the 'solution' theory of Murray, can account for the formation of all such reefs and atolls though, when once formed, every reef has been moulded and modified by world-wide phenomena, such as a change in the relative levels of sea and land.

Stanley Gardiner has given us an admirable summary of this, his life's work, and of the conclusions that he has drawn from it, in his book "Coral Reefs and Atolls", a most valuable supplement to Darwin's own volume "On the Structure and Distribution of Coral Reefs". There is a special fitness in the award of the Darwin Medal for work of such "acknowledged distinction in the field in which Charles Darwin himself laboured".

### Hughes Medal

The Hughes Medal is awarded to Prof. George Ingle Finch, professor of applied physical chemistry in the Imperial College of Science and Technology, in recognition of his fundamental contributions to the study of the structure and properties of surfaces; and for his important work on the electrical ignition of gases.

Finch has carried out two important bodies of research in different fields, both involving electrical considerations in a fundamental manner. The first was a detailed study of the electrical ignition of gases, the second the application of electron diffraction to a wide range of chemical and physical surface problems.

In his work on electrical ignition, Finch not only elucidated the chemistry of the ignition of simple gaseous systems, but also was the first to develop the theory of the sparking ignition coil. His inductance component control interrupter has been used by the Radio Research Board for the production of single electromagnetic pulses. In the course of his ignition work, Finch developed, as a pioneer in Great Britain, the high-speed cathode-ray oscillograph.

In the field of electron diffraction Finch has developed the electron diffraction camera into an equipment giving results of high accuracy with speed and ease of manipulation. The Finch camera has found wide application outside his laboratory, and examples made under his direction have been installed, among other places, at the National Physical Laboratory, University College, London, the University of Brussels (two), and in the laboratories of Messrs. Ferranti and of other industrial research centres. The pictures which he has obtained with it are outstanding in beauty of detail. He has contributed notably to the interpretation of the electron diffraction pattern and has applied his methods to many problems of theoretical and practical importance.

Of special interest are Finch's studies of the relation between crystal size and lattice dimensions and, in the more practical field, his investigations into the effect of the substrate on adhesion of electro deposits, into the nature of polish and into the mechanism of boundary lubrication and the wear of sliding surfaces. In all these he has materially advanced our knowledge, and his work on sliding surfaces, in particular, has found important applications in engineering practice.

His work during the War has covered a variety of fields, some involving the application of electron diffraction. That which he has carried out as scientific adviser to the Ministry of Home Security, while less closely related to his normal lines of research, has been of the greatest value.

## ANIMAL PRODUCTION AND ANIMAL BEHAVIOUR

On Tuesday, October 24, the British Society of Animal Production held a discussion on the British sheep industry; on the morning of October 25, a joint meeting with the Institute for the Study of Animal Behaviour was held to consider the grazing behaviour of sheep and cattle; the Institute, on the afternoon of October 25, discussed the food preferences of dairy cows and the importance of the study of behaviour from the veterinary aspect.

The familiar classification of British sheep into hill,

lowland and Down types tends to split the industry into distinct sections, although it implies separation on ecological grounds or according to conditions of husbandry. In fact, as Prof. R. G. White clearly demonstrated in his opening general survey, the sections of the sheep industry in Great Britain are closely interrelated and interdependent, so that the industry must be considered as a whole, with that whole in turn forming an appreciable factor in the complex pattern of British agriculture. Although war-time food production policy has tended to relegate the sheep to a lowly place in the British livestock industry and to distract popular attention from its important role in British agriculture, we, as a nation, like mutton and lamb. Sheep consume home-produced grass, fodder crops and foods not suitable for human consumption, and are thus quite different from pigs and poultry. We have large areas of hill and mountain lands which under present conditions can only be exploited economically by sheep-grazing. The sheep of these areas are important not only in themselves but also because they are the basis on which the great majority of the 'flying flocks' of the lowland pastures are founded, and these in turn depend largely upon the arable flocks for the supply of rams for mating to the hill ewes and their crosses to produce fat lamb. If, after the War, we have to increase our home meat production, this will be done mainly by the sheep, and the sheep industry as a whole will be involved.

Mr. D. H. Dinsdale showed, from the economic point of view, that although there is a complementary relationship between hill and lowland sections of sheep farming, and recent trends have emphasized the importance of the foundation nature of the hill flocks, there is also a competitive relationship, as both tend to cater for the same market for meat. To this end the changes in the industry have been of character rather than extent. Most hill farms are small economic units and receive only a small proportion of their income from sheep and wool; the problems of a broad policy for improvement and rehabilitation would, therefore, affect many people. There are physical limits (soil, climate) to improvement as well as economic limits (price, capital expenditure); also, in the sheep enterprise on hill farms, questions of fluctuations in the annual lamb crop, of replacement of stocks (most hill flocks being self-maintained), and of selection for characters of hardiness and mothering ability, raise important biological considerations on which more data are needed. He concluded that no "single-track solution can be expected, of itself, to restore hill sheep to the place they should hold in a balanced farm economy".

In the ensuing discussion, the prime necessity was emphasized of a co-ordinated programme in Britain for improvement of stock and of land, for social betterment and co-ordination between forestry and agriculture in land use; knowledge is required of the efficiency of both sheep and grazing, of suitable ratios of cattle and sheep for successful grazing management, and of losses of efficiency due to inappropriate selection, to subclinical parasitism, and to low nutritional levels of pregnant ewes during winter.

The general lack of adequate data for framing policies was neatly exposed by Mr. T. L. Bywater, who presented a summary of the results of the University of Leeds crossbreeding trials. These have been carried out since 1898, first at Garforth and later at Askham Bryan, and bear upon the question of the most suitable kinds of stock for the flying flocks on long leys. Many different breeds and crosses of ewes were used, mated to different breeds of rams; records of fertility and of weight and age of lamb when sold have enabled a general comparison of the results of the various crosses to be made on a basis of the total live weight of lambs produced per ewe put to the ram. A significant feature is that smaller differences in results occur from different breeds of rams as compared with different types of ewes—in flying flocks the ewe is more important than the ram; moreover, the results from individual rams of the same breed vary more than between rams of different breeds. For desirability in a flying flock, the ewe should be thrifty, able to rear on the average about $1\frac{1}{2}$ lambs per year, have a sufficient milk yield to produce not less than 120 lb. live weight of lambs at six months or less, and be capable of bearing at least five lamb crops in her life-time. Under the conditions represented in these trials, such characters were found to be most fully expressed in 'North' (Border Leicester × Cheviot) and Masham (Wensleydale × Swaledale) ewes, while for general conditions such types as the Clun, Kerry Hill, Greyface (Border Leicester × Blackface), and Welsh crosses could be relied upon. For mating to such ewes the ram should be able to grow quickly and to fatten readily and be well developed in loin and leg; Suffolk, Oxford and Hampshire rams had been satisfactory, with Suffolks giving the most consistent results.

Mr. Bywater contended, and other speakers supported him, that it is necessary to have similar trials carried out in other localities before an enlightened policy can properly be devised. Among the allied problems to be taken into account are the quality of the lamb product, the most suitable methods of measuring productivity, profitability and depreciation, as well as the source of supply of ewes. In any event, the possibility of different combinations of ewes and rams gives advantages in adjusting production to the various local circumstances; fresh combinations of breeds may be well worthy of study.

The complexities of management of arable flocks were discussed by Mr. J. F. H. Thomas. This section of the industry has declined for economic reasons—lower grain prices, expansion of dairy cow production, high costs of labour and of cultivations. But in spite of these, arable flocks in the south of England enable the large areas of unfenced, unwatered land on the chalk formations to be utilized and the fertility of the ploughland to be maintained. So far as the sheep themselves are concerned, the important questions are those of the suitable types or breeds for commercial production, the standard of which is affected by the present low fertility. Over-specialization on high carcase quality has neglected the factors of high fertility and milking ability of the ewe. Mr. Thomas does not believe, although some of the subsequent speakers did, that the only future for a able flocks is to produce rams for crossing purposes. He sees a favourable prospect for the commercial meat-producing flock, provided that all conceivable sources of loss can be reduced, whether they are due to defects of management, to parasitism (to which the intensive system predisposes but which can be controlled largely by good husbandry), or to other diseases that are favoured by heavily stocked land. He considers that this most complicated branch of the livestock industry has as yet received little help at the practical level from the agricultural scientific worker—and the general trend of the subsequent discussion admitted this by implication, although the

advantages of phenothiazine in control of parasitic worm infestation were stressed.

The second day's proceedings indicated some of the ways in which scientific inquiry is throwing light upon practical problems, and in some cases leading to a reconsideration of attitude towards them.

Mr. John Hammond, jun., summarized the results of observations on the breeding season in sheep and its extension by treatment with pituitary extracts and pregnant mare serum, which induce ovulation in anœstrous ewes, but without heat at the first ovulation. This year it was found that stilbœstrol administration, following injection of mare serum hormone, failed to accelerate onset of heat, and that treatment with pregnant mare serum alone, followed by artificial insemination, did not lead to fertilization. The maximum lamb crop under practical conditions would be produced, without treatment, by mating in mid-October and again in February or March, when a second crop could be expected from about 25 per cent of the ewes; with successful hormone treatment, a natural mating in October could be followed by a second service in June.

Experiments at Cambridge on the feeding of pregnant ewes were described by Mr. L. R. Wallace, who showed that lambs from ewes allowed to lose weight during the last six weeks of pregnancy were significantly lighter at birth than those from well-fed ewes. Further, the milk yield of the former ewes was, both at the peak and throughout a sixteen-week suckling period, materially less than that of the second group. This greatly affected the growth of the lambs, which at sixteen weeks averaged 56 lb. and 72 lb. for the two groups respectively. The importance of the level of nutrition during late pregnancy was emphasized by the spectacular differences in size at birth of the lambs from groups of ewes which had been well fed either throughout or during the last two months of pregnancy, as compared with those which had been poorly fed throughout or for the last two months. The ewe's udder remains small, and little affected by feeding level, until ninety-one days of pregnancy; after this the degree of its development is markedly influenced by the nutritional level of the ewe.

Detailed observations on an inbred Romney flock enabled Dr. Nancy Palmer to present a general picture of wool-growth on a unit area of skin; the length of fibres is determined by follicle density at birth, the subsequent rate of skin expansion, and the weight of wool produced. The last factor is found to be the same every summer for all sheep, of any age, in this particular flock.

The practical importance of Mr. Wallace's findings is patent; those of Dr. Palmer were shown by several speakers to throw light upon some of the factors which have to be taken into account in selecting for density of fleece-covering on one hand and increased body-size on the other.

The succeeding papers were concerned with an aspect of livestock management which has received relatively little direct attention. Though conditions of animal behaviour have long been tacitly recognized as affecting experimentation and practical procedures, apparently only in recent years have they been subjected to scientific study, interpretation, and even deliberate exploitation. For example, Dr. J. E. Nichols referred to one of a series of investigations on the problem of drought-feeding in Western Australia, in which the preferential grazing of the sheep and their habits of necessary and unnecessary movement were studied parallel with observations on the food values and ecology of different forms of *Acacia aneura*. As a result, it proved possible to devise, in the particular circumstances, a practical, and economical, procedure for maintaining the condition of the stock and preventing losses by exploiting the highly developed discriminatory sense of the sheep for the most nutritious shrubs and conserving their expenditure of energy by restricting their travelling as much as possible.

This evoked instances of how similar behaviour patterns could be examined in relation to preferential grazing in Britain, and consequently to the selection of more highly utilizable fodder plants and grasses, and to increasing the efficiency of food utilization under hill conditions as well as in folded flocks.

Mr. A. N. Worden communicated a résumé of Prof. Johnstone-Wallace's studies at Cornell on the grazing habits of beef cattle. From observations on the time taken in grazing and travelling, on the mechanics, methods, and selectivity of grazing, and on the frequency of defœcation, principles of rotational use and management of the pastures can be formulated. While the idea and practice of rotational grazing are not new, it has become clear that detailed investigations on these lines are necessary to enable the most efficient utilization of the various patterns of pasture-growth to be made, if only to overcome the loss of efficiency due to the rapid reduction of herbage consumed as the amount available for consumption is reduced by grazing. Our present ideas of what constitutes good pasture and good management of stock and pasture may require modification.

A similar view in relation to byre feeding emerges from Mr. K. L. Blaxter's observations on the habits and food preferences of dairy cows; refusals of food may occur before the mechanical satiation of the digestive tract, which places an upper limit on appetite, is reached. Broadly, food preferences are in the order: young grass, excellent quality hay, certain protein cakes and cubes, green fodders and roots, certain cereal and protein meals, average hay, then cereal chaff and straw. Moreover, the rates at which different foods are eaten, and at which different cows eat, vary greatly, the differences being most noticeable with bulky foods. Since the most nutritious foods are taken first and eaten most rapidly, these considerations must certainly affect herd rationing, where individual feeding is impossible through lack of adequate housing and facilities.

Some of the variables in this field are easily recognizable, others are as yet less obvious; examples of both kinds were suggested in the discussions which followed these papers. Thus a fertile ground was prepared for Dr. J. T. Edwards' analysis of the development of the study of animal behaviour and its general importance from the aspects of natural history and psychology, as well as in its didactic and economic considerations. In respect of the last, he instanced the work at Cornell, that of Stapledon (see *Vet. Rec.*, June 3, 1944), and Walton's observations on artificial insemination. Other speakers gave further examples of the necessary extension of the general approach, especially with regard to questions of degree and spread of parasitism in relation to grazing and other habits; these served to strengthen Dr. Edwards' plea for provision for systematic research on animal behaviour at institutes dealing with problems of animal husbandry and agronomy, and for the incorporation of appropriate courses at least into the veterinary curriculum. J. E. NICHOLS.

# OBITUARIES

## The Right Hon. Lord Moyne, P.C.

IN the preface to "Atlantic Circle", Lord Moyne says that had it not been for the South African War (for which he volunteered instead of going to the university) he would have become a biologist. A man endowed with his gifts of character and intellect, reinforced by a tireless energy and ample means, could scarcely have failed to make his mark. As it was, science had to take second place as an intermittent hobby pursued in the intervals of an exceptionally strenuous public life; and it was not until the last few years before the War that Lord Moyne was able to indulge more fully his taste for the biological sciences, among which anthropology took a prominent place.

Lord Moyne made a number of voyages in his steam yacht *Rosaura*, of which the last two, in 1935–36 and 1938, were scientifically the most important. These were no pleasure cruises. They had as their main objects the collection of ethnographical, archæological and zoological records and specimens for the British Museum and the London Zoo, and these objects were pursued with Lord Moyne's characteristic zeal, efficiency and courage. Danger seemed to attract rather than to repel him. At any rate, he was never afraid to take risks which seemed justified by the end in view, and it was only by great skill and (it must be admitted) a fair spice of luck that disaster was averted on each of these expeditions, which involved the wrecking of his two launches in New Guinea and damage to his yacht in the pack-ice off Greenland.

These two expeditions yielded a rich harvest, which included a splendid series of photographs taken by Lady Broughton, and colour films of great beauty and scientific interest. Out of the large ethnographical collection from New Guinea and the East Indies made in 1936, the British Museum received as a gift more than three hundred selected specimens, as well as photographs, all of a kind new to science or not hitherto represented in the national collection. The majority were from the almost unexplored southern regions of Netherlands New Guinea and from the little known Sepik and Ramu Rivers of the Mandated Territory. They included many objects of large size such as carved house posts, paddle spears and 18-ft. long blowguns, the safe transport of which would have been beyond the power of the ordinary collector without a yacht. From the 1938 expedition the British Museum received a very large and interesting collection of antiquities, chiefly pottery, excavated in the Bay Islands, Honduras. Other leading ethnographical museums including those of Oxford and Cambridge, and the Royal College of Surgeons, received a share of the spoils. Before the dispersal of his collections, Lord Moyne arranged attractive exhibitions of them at his house in Grosvenor Square (see *Man*, No. 121; 1936; and No. 71; 1938).

Lord Moyne was the first to publish records of a group of 'pygmy' folk from the Aiome Mountains on the Upper Ramu River, the average stature of which (based on a small number of individuals) was the lowest ever reported from New Guinea. These were described in his book "Walkabout", and briefly in *Man* (No. 121; 1936), while a detailed description of their material culture, written in collaboration with Miss K. Haddon, appeared in the *Journal of the Royal Anthropological Institute*, 66 (1936). Illustrated notes on some decorated shields and other specimens were published in the *British Museum Quarterly* (8, No. 129 and 11, No. 89).

Although written in narrative form, Lord Moyne's books, "Walkabout" and "Atlantic Circle", contain much scientific information, the value of which is increased by the accompanying photographs. There is also an introduction by the late Dr. A. C. Haddon and an appendix on the human crania by Dr. A. J. E. Cave in the former work. As an example of Lord Moyne's swiftness in action, it is worth mentioning that these volumes were each written and published within a few months of his return to England.

Lord Moyne had been for a number of years a fellow and a generous benefactor of the Royal Anthropological Institute, in the work of which he took a lively interest. He was elected a member of its Council in 1942. Only recently he had privately discussed his ideas for promoting archæological research in South America, particularly the highlands of Peru, either by an expedition or other means after the War. His untimely death has thus cut short a career in which his services to science, already considerable, would certainly have been continued and added to in the post-war years. H. J. BRAUNHOLTZ.

LORD MOYNE'S public activities left little time for detailed zoological work, but he had a life-long interest in the subject, and helped in many ways to advance our knowledge of general natural history and marine biology. He was for many years president of the Marine Biological Association and took a leading part in recent developments of the Plymouth Laboratory. In addition he was a valued member of the Council of the Zoological Society of London, and a generous donor to the collections in the Gardens.

Lord Moyne's main contributions to zoological science were the results of his yachting cruises to various parts of the world. On these he was generally accompanied by other naturalists, the Hon. Anthony Chaplin on the 1936 cruise, Captain Jean Delacour and Dr. John Colman in 1938, and Lady Broughton, whose excellent photographs help to illustrate his two books. Large and valuable collections of mammals, birds, reptiles, etc., were brought back either alive or carefully preserved, most of the live specimens being presented to the Zoological Society, and the preserved material to the British Museum (Natural History).

Among animals obtained on the cruise to New Guinea, a list of which is given in an appendix to "Walkabout", many, including two Komodo dragons, are still on view in the London Zoo. The collections of live animals brought back on this cruise alone and presented to Regent's Park included no less than sixteen species not previously exhibited in Britain.

All those who enjoyed the privilege of working with Lord Moyne have been impressed by his remarkable gifts, of which perhaps they will remember longest his thoroughness, his unfailing sincerity and his genius for friendship. EDWARD HINDLE.

WE regret to announce the following deaths:

Prof. D. MacCallum Blair, regius professor of anatomy in the University of Glasgow, on November 10, aged forty-eight.

Mr. E. V. Suckling, an authority on water purification and author, with J. F. Beale and J. C. Thresh, of "Examination of Water and Water-supplies", on November 16, aged fifty-one.

# NEWS and VIEWS

## Royal Society: Anniversary Meeting

THE customary anniversary meeting of the Royal Society took place on St. Andrew's Day, November 30, and the main part of the address by the president, Sir Henry Dale, is printed on p. 724 of this issue of *Nature*. In addition, Sir Henry referred to other matters, more of a domestic character. Prof. A. V. Hill's mission to India, to advise on science in general and a new programme of research and its applications, occupied the prominent place justified by the unqualified success which has attended it. A special meeting of the Royal Society was held in India, the first to be held outside Great Britain, and eventually a mission consisting of six of India's scientific leaders came to Britain, as the first stage of a tour extending to Canada and the United States, to see for themselves the scientific activities and organization with which the demands of war are being met and preparations being made for the tasks ahead in a largely devastated world. The members of the Indian mission used the rooms of the Royal Society as headquarters, and shortly before they left they were received by the King and Queen, who thus showed their interest in the promotion of closer understanding and comradeship in science between India, Great Britain and the whole of the British Empire.

Sir Henry Dale then turned to plans which are being made for increased provision for research in Great Britain. Last year he announced that the Royal Society had appointed a committee to consider the prospective needs of fundamental researches in physics. As the result of representations from other branches of science, a series of other committees was appointed, to consider the requirements in chemistry, biology, geology, geophysics, geography and mineralogy. The inquiries of these committees have been directed towards the advancement of knowledge without immediate or even implicit reference to practical needs or objectives; this was decided, not because of any inferior status or interest of applied research and related investigations, but because it is felt that such researches are already receiving support from the three Advisory Councils and are more likely to attract support from private benefactors. Sir Henry also referred to the problem of State accommodation for the principal scientific societies, with which he dealt in his address last year. The Royal Society was asked by several of the specialist societies to take up the matter, and a deputation was received by the Lord President of the Council, the Chancellor of the Exchequer and the Minister of Works and Buildings, on behalf of the Government. The case for the inclusion in any scheme for the rebuilding of London of a centre adequate to house the principal scientific societies was presented, and the deputation was asked to furnish quantitative data as a basis for further consideration of the question.

## Science and National Welfare

IN his address on receiving the Priestley Medal of the American Chemical Society on September 13, under the title "Science and the National Welfare" (*Chem. and Eng. News*, 22, 1642; 1944), Dr. J. B. Conant suggested that one of the many ills of the world seems to lie in the fact that certain aspects of accumulative knowledge, roughly what we call science, are often substituted for philosophy, while certain aspects of philosophy (a large part of the social sciences) are considered as science. If the United States is to live up to its responsibilities in the post-war years, it must foster all learning—accumulative knowledge, philosophy and poetry, including literature and the fine arts. So far as is humanly possible, all the potential talent in these manifold activities must be recognized at an early age and given adequate educational opportunity. Dealing more specifically with the physical sciences, Dr. Conant stressed the dependence, here as elsewhere, of the rate of advance on the number of really first-class men engaged, and he urged the institution of a national scholarship programme for young men who gave promise of becoming leaders in science and technology. For the most effective scientific advance in the applied fields, he believes there must be keen and strong rivalry between a number of strong and independent groups, but since we must look to the universities for the fundamental advances to be applied later and for the trained men required, industrial concerns and research institutes should beware of making too heavy demands on the universities for either time or their most promising men. Again, the mobile striking power of scientific talent required to exploit new advances resides ideally in the universities, but for the last twenty-five years the American universities had suffered from two great evils: their system of making life appointments, which so often fails to distinguish between men of real ability and men of medium competence; and the tendency to overburden the former with undergraduate teaching. Dr. Conant looks to the professional societies to play a leading part in forming the public opinion required to correct both these faults. With regard to funds, Dr. Conant believes it is more important for the universities to be able to find really first-rate investigators worthy of support than to find funds to support investigations.

## Scientific Film Association

THE first annual general meeting of the Scientific Film Association was held on November 25 in London. The chairman, Mr. Arthur Elton, proposing the adoption of the annual report, stressed the need for critical appreciation in the field of scientific films. He pointed out that the world of publishing has an elaborate organization for criticism and documentation of every book directly it is published; without some such machinery, the film will remain an ephemeral thing instead of being part of our national culture. He suggested that this deficiency in the scientific film might be made good by the Scientific Film Association, which is now publishing a catalogue of such films. Mr. Elton said that a North of England Section has been formed of the Association and that considerable interest has been shown in the United States and Canada. The Canadian Government has appointed a representative in Ottawa to cater for interest there in scientific films. Mr. Elton hopes that the Association will play its part in the international exchange of information by films. In the discussion which followed, members stressed the importance of developing the work of the standing committees of the Association dealing with medical, educational and industrial films. The problems of criticism and appraisal of scientific films were discussed and a request was made for specimen programmes for scientific film societies. A short film on Brownian movement made at the Glasgow Technical College, and the new film "Children of the City" and two

British Council films from the Central Film Library, "Life Cycle of the Maize" and "Development of the Rabbit", were shown.

## Russian Astronomy Resurgent

A TELEGRAM from Moscow gives the news that the Astronomical Council of the Academy of Sciences of the U.S.S.R. has already made a start on the task of rebuilding those Russian astronomical institutions which have suffered at German hands. Plans are being made both for the reconstruction of wrecked observatory buildings and for the design of new ones. A workshop under the direction of Prof. D. D. Midsutov, builder of the telescope with all-spherical surfaces, has been organized for the design of instruments and construction of scale models. The rebuilding of Poulkovo Observatory will begin in the near future: the new buildings, especially that which will house the great refractor, are designed to meet all the requirements of modern astronomical technique.

A site has been selected for the projected Central Asiatic Observatory on Zaili, a spur of the Ala Tau Mountains near Alma Ata. This observatory is not to be confused with the new astrophysical one, plans of which have already been drawn up, which in its scope and equipment is to be on a level with the best modern observatories. The site for this latter institution will probably be in the Crimea. The Ukrainian Academy of Sciences has decided to build a new observatory near Kiev, and Simeiz Observatory is already being rebuilt. In Moscow an astronomical laboratory is being established where visiting astronomers will be able to calibrate their photometric apparatus. The Leningrad Astronomical Institute will in future engage in purely theoretical work, including an attack on some problems in celestial mechanics, and will publish such periodical works as annual ephemerides.

## Total Solar Eclipse of June 9, 1945

A SOVIET broadcast announces that a commission set up by the Academy of Sciences of the U.S.S.R. to observe the total solar eclipse of June 9 next year has opened its first plenary session in Moscow. Prominent astronomers from Moscow, Leningrad, Kiev and other cities are taking part in the scheme. The band of totality passes from America through Norway, Sweden and Finland, crossing into Soviet territory near Lake Ladoga, and then stretching through Yaroslavl, Ivanovo, south of Gorki and Kuibyshev and north of Uralsk. The longest period of totality in the U.S.S.R. will be near Lake Ladoga, where it will last 61 seconds. Twenty Soviet expeditions are being organized. The Sternberg Astronomical Institute and similar bodies in Kiev, Kharkov and Kazan are to take part. Most of the sites of the expeditions are concentrated in the areas of Rybinsk and Yaroslavl. Preparations for observing the eclipse are also well forward in Sweden. A paper by Grönstrand, which is to appear in the *Annals* of the Stockholm Observatory, gives the circumstances of the eclipse in northern Sweden, and a party led by Lindblad plans to observe the flash spectrum.

## University of Melbourne

THE trustees of the estate of the late E. L. Baillieu have given the University of Melbourne £A105,000 for a new library to commemorate Mr. Baillieu's brother, the late W. L. Baillieu.

The following appointments have recently been made: Dr. L. H. Martin, formerly associate professor of physics in the University, but recently on leave for special duties under the Council for Scientific and Industrial Research, to be professor of physics; Dr. E. S. Hills, hitherto associate professor of geology in the University, to be professor of geology and mineralogy; Dr. S. Dattilo Rubbo, hitherto senior lecturer in bacteriology in the University, to be professor of bacteriology.

## Director of Army Education

BRIGADIER CYRIL LLOYD has been appointed director of army education under the Director-General, Mr. P. R. Morris. Brigadier Lloyd was educated at Brighton Grammar School and at the University of London, where he took his B.Sc. with first-class honours in 1926. He taught at Sir George Monoux Grammar School and later at Brighton Grammar School until the outbreak of war.

## Announcements

MR. D. A. OLIVER, research director of William Jessop and Sons, Ltd., and J. J. Saville and Co., Ltd., Sheffield, while continuing in this position, has also been appointed director of research to the Birmingham Small Arms Group, of which Jessops and Savilles form part. The B.S.A. Group research activities, in addition to being carried on in the existing laboratories situated at the different works of the Group, notably the Daimler Co., Ltd., Coventry, the B.S.A. Co., Ltd., Small Heath, Birmingham, and B.S.A. Tools, Ltd., Birmingham, are to be considerably expanded. Recent additions to the research staff include Dr. A. J. Bradley, formerly of the Cavendish Laboratory, Cambridge, and Mr. P. H. Lawrence, formerly of the Ministry of Aircraft Production, London.

THE Clough Memorial Research Fund, which was instituted in 1935 for the purpose of encouraging geological research in Scotland and the north of England, provides a sum of approximately £30 annually. Applications for grants are invited for the period April 1, 1945–March 31, 1946, and should state (1) the nature of the research to be undertaken; (2) the amount of grant desired; (3) the specific purpose for which the grant will be used, for example, travelling expenses, maintenance in field, excavation of critical sections, etc.; (4) whether any other grant-in-aid has been obtained or applied for. Applications must be in the hands of the Secretary, Clough Memorial Research Fund Committee, Edinburgh Geological Society, Synod Hall, Castle Terrace, Edinburgh, not later than March 1, 1945.

THE Summary of Current Technological Developments issued by the U.S. Department of Labour is prepared each month by the Productivity and Technological Development Division of the Bureau of Labour Statistics. Started at the end of 1941, it summarizes recent changes in processes, materials and manufacturing techniques as reported in current trade and technical periodicals, of which about two hundred are now covered each month. In addition to short abstracts of the articles or notes appearing in the periodicals cited, brief special reports are frequently presented on matters of current interest, based on a number of sources or on the work of the Division. The February 1944 issue, for example, includes a fifth article in a series on labour utilization, dealing with employee training and upgrading.

## A Method of Differentiation of Crude Oils based on Chromatography, Capillary Analysis and Fluorescence in Ultra-violet Light

CRUDE petroleum and the refined oils obtained from it fluoresce strongly in ultra-violet light. This property has recently been utilized for the differentiation of various types of crudes from one another and from refined oils or artificial mixtures prepared to resemble natural crudes[1 2 3]. The oil is either dissolved in a non-fluorescent solvent or spotted on a filter paper and fluorescence noted. Several crude oils from a particular field, some samples of refined oils, and two artificial crudes were examined using a Hanovia Universal fluorescence lamp as the source of ultra-violet light. The samples of refined oils could be readily distinguished from the crudes; but only minor differences were observed between the real and artificial crudes.

A technique based on the use of chromatography and capillary analysis on filter paper strips has been developed and found to be more satisfactory than fluorescence analysis of crude oils as such. The use of chromatographic adsorption analysis for testing asphalts and bitumens has recently been reported by Grader[4]. We adopted the following procedure. The chromatogram was formed on a column of Brockmann alumina from a dilute solution of the oil in petroleum ether (40–60° C.). After washing the column with the same solvent until a colourless filtrate appeared, it was dried by suction and then benzol percolated

through it. The filtrate was collected in a separate receiver, and washing with benzol continued until a colourless filtrate was again obtained. This cycle of operations was repeated with chloroform. Different fractions of oils obtained by evaporating the extracts were dissolved in chloroform and the fluorescence of the solutions compared at equal concentrations. Capillary analysis was then carried out. Some results are given in the accompanying table and chart.

The oil samples gave blue fluorescence when dissolved in chloroform; but the fractions separated by chromatography showed marked differences in fluorescence colour.

These investigations have been carried out with the aid of a grant from the Assam Oil Co., Ltd. The method is being developed further. Our thanks are due to Mr. P. Evans and Mr. A. Reid for their help.

## Amides, Imides and Peptides

IN suggesting the term 'polypeptides' for describing condensates of amino-acids at large, Dr. Jordan Lloyd[1] is seemingly extending the meaning of the word beyond that originally proposed by Emil Fischer[2], who introduced it for the condensates of $\alpha$-amino-acids. Indeed, 'peptide' was not proposed for the link –CONH– but for the residue –CH*R*–CO–NH–, as is indicated by the use of 'dipeptide' for glycylglycine, which contains only one –CONH– group. Fischer, in his original lecture[3], put forward the proposal that by analogy with known distinctions made in carbohydrates between disaccharides, trisaccharides, etc., compounds of the glycylglycine type should be termed dipeptides and the higher condensates of amino-acids termed tripeptides, tetrapeptides, etc.

Dr. Jordan Lloyd's proposal, in addition to departing from Fischer's original conception which has been preserved in general usage, would bring within the scope of the term such polycondensates as those obtained from $\omega$-amino-acids, for example, $\omega$-aminocaproic acid. We agree that it is desirable to avoid confusion between proteins and nylons, but we think that Dr. Lloyd's suggestion would lead to more confusion in that it would not help in differentiating between condensates of $\alpha$-amino-acids and those of $\omega$-amino-acids, which must be classed as nylons[4].

It is misleading to say that nylon chemistry has its origins in organic chemistry: it is a part of organic chemistry, and not a different subject. Dr. Lloyd's complaint would seem to be based on a lack of knowledge of recent history. The word nylon is used as a short *generic* term[5] for what the inventor of the compounds, Carothers, described, prior to the introduction of the word nylon, as polyamides[6]; that is, the term polyamide is older than the term nylon.

To call the group –CO–NH– an amide or amido group is not wrong: to quote from the "Instructions to Abstractors" of the Chemical Society (see also ref. 7) "when . . . the $NH_2$ group is substituted with an acid residue such as acetyl it becomes acetamido, etc.".

Dr. Jordan Lloyd's definition of an imine as a compound containing the $>NH$ group only represents general usage when the group is part of a cyclic system, for example, as in ethylene-imine and *cyclo*-hexamethyleneimine, or present as a : C=NH group. Similarly, imides are *cyclic* secondary amides of dibasic acids[8].

We agree with Dr. Jordan Lloyd that it is not so easy to use existing terms, or to devise new terms, for purposes of classification in organic chemistry as it is in, for example, botany; but we do not agree that clarity will be brought into any relations when 'polyimide' is suggested as a general term with a definition which would seemingly include the well-known hydroxynaphthoic arylamides.

It is an objection to polyamide that it offers itself as a generic term also for the polymers of methacrylamide $CH_2 : C(CH_3)–CO.NH_2$ but, we think, few one-word terms are used without a context.

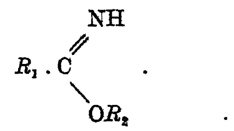
[8] Sidgwick's "Organic Chemistry of Nitrogen", Taylor and Baker, p. 152 (Oxford Univ. Press, 1942).

DR. JORDAN LLOYD is wrong in her conception of the nomenclature of imides and imines. While organic chemists will agree with her dictum that substances carrying the $–NH_2$ group are amines, those which carry the $>NH$ group are not necessarily imines. Thus, dimethylamine, $(CH_3)_2NH$, has such a group, and is still an amine; surely an imine must contain the structure $>C=N–$, as in the imino-ethers



With imides and amides the problem is similar; if Dr. Jordan Lloyd is correct in her view, any substance containing the –CONH– group would be an imide. Thus, on conversion of acetamide, $CH_3CONH_2$, to its methyl derivative $CH_3.CO.NH.CH_3$, a change in nomenclature would also take place, and the substance would be known as 'methyl acetimide'. This is quite in opposition to current practice and would be a most undesirable feature of nomenclature. Such substances are properly known as 'substituted amides'. The conception associated with imides dates from the recognition by Wurtz[2] in 1854 that amides could react as if derived from either of the structures I or II, and this persists in the 'lactam-lactim' nomen-

$R.CO.NH_2$ (I) $\quad R.C(=NH)OH$ (II)

clature used by Baeyer for the parallel case of isatin and its homologues.

It is clear that the term 'imine' should be confined to substances in which the $>C=N-$ is present, and that 'imide' should be reserved for derivatives of the enolic form of the amide structure and for the cyclic amides of dibasic acids. Substances of the structure $R_1CONHR_2$ should be termed 'substituted amides'. The term 'polyamide' for nylon is, therefore, correct.

[2] Wurtz, *Jahresb.*, 566 (1854).

IN reply to the above communications, I wish to say that the main point in my complaint is that in two closely allied fields of chemistry the connecting link –CONH– is being called by two different names, namely, 'amide' and 'peptide', and that the expression 'amide (or amido) group' is being used to cover both the connecting –CONH– and the terminal group $-CONH_2$, both of which are present in proteins.

For example, in a recent paper by P. J. Flory[1] dealing with three-dimensional polymers and the theory of gelation, in the section on protein gels he refers to "amide-amide hydrogen bonds" and quotes a paper by Myers and France. Reference to the latter paper[2] shows that these workers talk of hydrogen bond formation (with acetic acid) at "the loose ends of the salt-bridges after neutralisation has permitted them to separate", and of the "possibilities of hydrogen bond formation at each peptide link". They do not refer to 'amides' at all. When Dr. Astbury talks of an 'amide-hydroxyl' hydrogen bond in keratin, he means a side-chain link between the group $-CONH_2$ and OH.

Some of the correspondents also appreciate the difficulty. I am not an authority on organic nomenclature, and am willing to accept any ruling which would lead to clarity and be acceptable to the Chemical Society. As regards the past history of polypeptides and synthetic polyamides, this has not escaped my attention, but it does not of itself suggest how to deal with the future.

## Endocrine Reaction to Tissue Injury

IT has been reported previously that tissue damage produces in animals a state of resistance to the lethal effects of a subsequent trauma[1,2]. Resistance, as detected by the decrease in post-traumatic mortality, was accompanied by the following functional changes: inhibition of the normal release of histamine from blood cells[3]; shortening of the bleeding time; and increase of the capillary resistance[4]. All changes could be transferred to normal animals by injection of the serum of traumatized animals. It was also shown that the substance present in the serum and responsible for the resistance was produced by the pituitary and acted through the adrenal cortex[4].

Further investigations have been carried out, using the shortening of bleeding-time as test. Trauma, as well as injection of serum from traumatized animals, reduces the mean bleeding-time by about 40 per cent in groups of guinea pigs and rats. In hypophysectomized, adrenalectomized or splenectomized animals, however, neither trauma nor the injection of traumatic plasma produces a shortening of bleeding-time.

The part played by various tissues was further tested by studying the action of tissue extracts on bleeding-time. Of eighteen tissues investigated, only the extracts of pituitary, adrenals and spleen shortened bleeding-time. The same effect was observed with purified products from these organs: corticotrophic hormone of the pituitary and whole cortical extract (synthetic desoxycorticosterone was inactive). A spleen extract was prepared which shortened bleeding-time in a dose of 0·02 μgm. per kgm. body weight. Chemical identification of the latter is being attempted.

It has also been shown that the pituitary hormone is without effect in adrenalectomized or splenectomized animals. Adrenal extract had no action in the absence of the spleen, but spleen extract was still active in animals deprived of pituitary, adrenals or spleen.

Selye[5] observed hypertrophy of the adrenals in the 'adaptation' phase of the 'alarm reaction' which can be elicited by tissue injury. It is also known that adrenalectomized animals are particularly sensitive to 'shock' conditions[6]. The intervention of the pituitary in protection against these conditions was suggested by Reiss, Macleod and Golla[7]. Perla and Marmorston put forward the idea that the spleen might play a part in the resistance to infections[8]; but the facts mentioned above supply probably the first experimental proof of an endocrine function of the spleen.

The results of the experiments reported here point to the existence of a physiological mechanism responsible for the resistance to lethal effects of trauma. The pituitary responds to tissue damage by the secretion of corticotrophic hormone, which determines the release of an adrenal product stimulating eventually the secretion of the splenic substance. The mode of action of the latter is not yet known; some of its effects suggest either a change in the reactions of the capillary wall, reducing perhaps the escape of fluid into the tissues, or the inhibition of the release of toxic substances from certain cells.

## A Crystalline Serum Muco-Protein with High Choline-Esterase Activity

In a recent article[1], Bader, Schütz and Stacey state: "It appears to be an undecided question whether choline-esterases from different tissues, such as blood and brain, are identical".

Bader and his associates must have failed to note that it has definitely been established that the cholinesterases from different tissues are not identical. The investigations reported by us[2] have conclusively demonstrated the existence of two distinct cholinesterases, a specific or true cholinesterase and a non-specific or pseudo-cholinesterase. Erythrocytes and brain[3] throughout the vertebrate kingdom contain true cholinesterase only, while a mixture of both enzymes is present in most of the sera[4] and tissues[3] of the many mammals investigated.

Furthermore, Bader and his co-workers report that they have isolated from horse serum a crystalline muco-protein with a cholinesterase activity 20–25 times higher than that of the original serum. As the purified enzyme preparations from horse serum described by one of us[5] are about three hundred times more active than their crystals, it seems likely that at least 299 out of 300 parts of these crystals, that is, 99·7 per cent, represent inert material.

Since Bader *et al.* are inclined to the view that the great discrepancy between their results and our own might be due to the use of different methods of assay, we feel that an exchange of samples, giving both parties an opportunity of comparing the activity of the two preparations by their own test, would be the most satisfactory solution of the controversy.

## An Effect of Overdosage with Corticotrophic Pituitary Extract on the Rat Kidney

Recent progress in the purification of the corticotrophic fraction of the anterior pituitary lobe (the preparations contain 24–48 cortic-lipoid units per mgm.) has made it possible to inject rats with very large doses of this hormone. While investigating the effect of such large doses, it was noticed that the kidneys of animals intraperitoneally injected with a dose exceeding 100 units presented a picture which differed considerably from that of the kidneys of the control rats.

Kidneys of rats injected with the corticotrophic hormone showed the following abnormalities. Macroscopically, the kidneys appear pale, mottled and swollen, with a tense capsule. This observation was borne out by a comparison of the weight of kidneys of injected animals with that of the kidneys of controls. It will be seen from the accompanying table that, after injection of doses of corticotrophic hormone ranging from 4 to 24 mgm., weight increases of 14–46 per cent have been found.

| Treatment | No. of rats | Combined body weight of whole group (gm.) | Combined weight of kidneys (gm.) | Combined weight of kidneys as per cent of combined body weight | Increase in kidney weight (per cent) |
|---|---|---|---|---|---|
| Controls | 3 | 125 | 1·77 | 1·41 | |
| 24 hours after 8 mgm. intraperit. | 3 | 121 | 2·32 | 1·91 | +35·5 |
| Controls | 3 | 135 | 1·74 | 1·29 | |
| 5 hours after 4 mgm. intraperit. | 3 | 145 | 2·45 | 1·69 | +32 |
| 3×4 mgm. in 48 hours | 3 | 126 | 2·38 | 1·89 | +46·5 |
| Controls | 3 | 129 | 1·8 | 1·39 | |
| 3×4 mgm. in 48 hours | 3 | 122 | 2·1 | 1·68 | +22·4 |
| 6×4 mgm. in 72 hours | 3 | 133 | 2·6 | 1·92 | +38·1 |
| 5 hours after 12 mgm. intraperit. | 3 | 132 | 2·21 | 1·59 | +14·4 |

*Histological findings.* In kidneys of rats injected with 1 mgm. of extract per animal and killed after 12 hours, the main pathological change consists in a patchy necrosis of the tubules of the glomerular zone of the cortex (see photomicrograph). There is marked swelling of the tubular epithelium, usually sufficient to obliterate the lumen, nuclei are absent or shrunken and pyknotic, and the cytoplasm stains a light pink with eosin without showing the granularity of cloudy swelling. Staining with Sudan III or IV shows deposits of lipoid granules in a minority of these tubules; but fatty change is not a conspicuous feature, nor do these kidneys contain anisotropic lipoid. The glomeruli are somewhat enlarged and may exhibit a slight cellular swelling and capillary dilatation. With larger doses (for example, 8 mgm. after 12 hours) in addition to the changes described above, which are now more marked in the case of the glomeruli, there are larger areas of infarction, with necrosis of all elements of the cortex, corresponding to the areas of hæmorrhage observed macroscopically.

The changes described could be seen as early as five hours after injection of the high doses of the corticotrophic hormone, and they seem to be fully developed twelve hours after the hormone administration.

NECROSIS OF TUBULES IN THE GLOMERULAR ZONE OF THE CORTEX OF RAT KIDNEY 12 HOURS AFTER 1 MGM. EXTRACT INTRAPERITONEALLY. EHRLICH'S HÆMATOXYLIN AND EOSIN. × 270.

Considerably larger doses of egg albumen, peptone and dried whole pituitary gland suspensions failed to produce similar changes in control animals.

In a further series of experiments, a number of epinephrectomized rats were injected with high doses of the corticotrophic hormone preparation. The kidneys of some of these animals showed similar though less pronounced changes to those observed in rats with intact adrenals.

The occurrence of these kidney changes after injection of the hormone might be ascribed to either of two factors, if it is possible to rule out a direct toxic action due to the concentration of some substance during the process of purification. These possibilities are: (*a*) an effect of the anterior pituitary hormone on the accessory adrenals; (*b*) a direct action of the purified corticotrophic hormone on the kidneys.

The first possibility would appear to be more acceptable, as Selye[1], with overdosage of desoxycorticosterone acetate, has produced nephrosclerotic changes in the kidneys of young chicks. Other investigations[2] point in the same direction.

It may also be remembered that pathological changes of the kidneys and the kidney function have been observed in cases of Cushing's syndrome, a disease in which a hyperexcretion of corticotrophic hormone[3] and of cortine[4] has been demonstrated.

## Optical Phenomena in the Atmosphere

THE "Solar Halo Phenomenon" described by G. H. Archenhold in *Nature* of September 30 was referred to in recent correspondence in *The Times* and was explained in a short article by me in *The Times* of August 31. The occurrences of August 9 seem to have been particularly striking.

Accounts from meteorological observers have made it fairly certain that the "dark bands moving like waves" or ripples across solar optical phenomena are connected with sound waves from explosions. I saw some in France during the War of 1914–18 on the occasion of a series of big explosions, though at that time the connexion with sound waves was not appreciated[1].

It seems that the sound waves passing through the air can affect two types of optical phenomena: (1) the type such as iridescence which depends on diffraction of light through minute water droplets; and (2) the type depending on reflexions in ice crystals floating with their axes in a fixed direction.

In the first type, as a result of the sequence of adiabatic warmings and coolings produced in the cloud by the explosion waves, the sizes of the cloud droplets diminish and increase respectively. With the changes in the size of the cloud particles, changes in the interference colours and thus in the iridescence are brought about. It might at first sight seem that changes in size of water drops could not take place sufficiently quickly to render sound waves visible in this way; but according to theoretical calculations made by Findeisen and experiments on artificial fogs made by H. Mache about 1933, the rate of evaporation of water droplets can actually be sufficiently great in the very small droplets characteristic of thin, newly formed clouds.

In the ice crystal type of phenomenon, it is presumably the momentary displacements caused by the explosion waves in the lie of the crystal axes which cause the ripple effect. The angular speed of the ripples mentioned by G. H. Archenhold (5° per second) would give the velocity of sound at a distance of some 12,000 feet, though the height of the cloud trail was much more likely to have been about twice as great. The band width mentioned ($\frac{1}{8}$°) or the distance between bands ($\frac{1}{2}$°–1°) would correspond to a very low frequency sound which, however, is a characteristic of heavy explosions.

It may be relevant to mention here another kind of optical phenomenon which has recently been described in letters to *The Times* and discussed in an article on September 3 under the heading of "Flying Bomb Waves". Such waves have been seen by observers of nearby explosions and have been described as "a faint but distinct line in the form of a seemingly perfect arc centred on the spot where a bomb had disappeared". These effects are connected with the explosion wave within a few hundred yards of the explosion itself, and it seems that the curved line represents the hemispherical wave of compressed air. In this case the optical effect might arise either from evaporation of water droplets in cloudy air or even as a refraction (mirage) effect from the relatively steep gradient of air density. Calculation of the effect produced by a ton of high explosive suggests that either effect is physically possible up to a radius of the order of 500 yards from the exploding bomb, provided the bomb explodes before burying itself in the ground or in buildings, and assuming the observer to be suitably placed—say, half a mile distant—to view the effect.

Stonehouse, Glos.

[1] *Q. J. Roy. Met. Soc.*, **45**, 366 (1919).

THE arc through the sun described by Mr. C. J. P. Cave[1] can only, I fear, be identified with the horizontal circle and not with some rare tilted arc. Its identity is clear from the fact that it passed both through the sun and through the parhelia to the 22° halo, which have the same altitude as the sun. The impression of upward tilting, due to perspective, was unquestionably enhanced by the comparatively high sun and the small amount of the circle that was visible; a lower sun and a more extensive development of the circle make it clear that all parts of it are the same distance from the horizon. The apparent tilting is an effect with which Mr. Cave will certainly be familiar from observations of clouds.

I have advisedly used the word 'tilted', since the word 'vertical' is inadmissible in the sense used by Mr. Cave. Haloes are, of course, simply rays of light

with a particular orientation to the eye, but for convenience we regard them as having a definite location. The 22° halo, generally seen as a circle normal to the line from the sun to the eye, if seen in hoar frost soon after sunrise is so obviously on the ground that we say it is a horizontal hyperbola. Similarly the rainbow, when seen as a dewbow on ponds covered with an oily film, on cobwebs, or on delicate new-sown grass, becomes an ellipse. In general, halo phenomena are regarded as projected on the celestial sphere. A little consideration makes it clear that a horizontal circle through the sun, as it is progressively raised on the side away from the sun, becomes steadily smaller and finally disappears when its inclination to the horizontal is equal to the zenith distance of the sun.

Although the number of observations is too small to allow definite conclusions, it is of interest to note that the four well-developed horizontal circles that I have observed have all been in small cirro-stratus sheets far below the ordinary cirrus level, at some 5,000 ft. or less; of trace observations, one has been at low level in ice-crystal fog, three at high level, and three at doubtful heights. The brief life and sudden appearance and disappearance of Mr. Cave's display suggest a low level, and consequent high angular velocity, of the cloud.

The occurrence of these arcs in cloud believed to have originated from condensation trails is of interest to me because such trails sometimes seem to yield no arcs, which suggests that they may be made up of very small crystals, complex crystals, or sub-cooled droplets. Of nine sets of trails seen, five did not approach the sun, three yielded no arcs, and one yielded a brilliant circumzenithal arc. The aircraft that formed the latter trail was estimated to be flying at 3,000 ft. and a thin ice-crystal haze was present at the same general level, since a faint circumzenithal arc was present below small patches of alto-cumulus. It may be significant that the two possible orientations of crystals forming this arc (vertical axis of symmetry, and horizontal axis of symmetry with two side faces horizontal) are two of the possible orientations of crystals forming the horizontal circle (vertical axis of symmetry, horizontal axis with two side faces horizontal, horizontal axis with two side faces vertical, and horizontal axis with side faces randomly oriented). Perhaps readers in Britain, where condensation trails must have been only too common in the last five years, can give more information on optical effects in this type of cloud.

[1] *Nature*, **154**, 240 (1944).

THE letter of Dr. Savile and private correspondence I have had with Dr. Paul White convinces me that I must have been mistaken, and that what I saw on May 2 was a small part of the parhelic circle.

No doubt 'tilted' is a better word to use in connexion with halo phenomena than 'vertical'; but the latter term has been in use for a long time and did not originate from me.

## Cryoscopy of Solutions

A. V. Brancker, S. J. Leach and V. A. Daniels suggest[1] that $\theta$, the depression of the freezing point of a solvent by a solute of $m$ molal concentration, can be given by $\theta = Km^b$, where $K$ is the cryoscopic constant and $b$ a constant very nearly unity.

Such a relation, admittedly empirical, is fundamentally of an incorrect form because it cannot lead to the necessary thermodynamic requirement that $\theta/m$ is finite when $m = 0$, and furthermore, $K$ so defined is a cryoscopic constant at unit molality, a quantity smaller than the limiting or van't Hoff value. The ability of this relation to accommodate data over a wide range of concentration from 0 to 1 molal is apparent only. This agreement exists because $d\theta/dm$ and $\theta/m$, although identical at $m = 0$, diverge very slowly with increasing concentration, and $b$ is the ratio of these quantities.

It can be shown thermodynamically, for solutions obeying Raoult's law, that $m = \alpha\theta + \beta\theta^2 + \gamma\theta^3 + \ldots$, where $\alpha$ is the reciprocal of the van't Hoff constant, $\beta$ and $\gamma$ are functions of heat of fusion and its temperature coefficient. From this it follows that $b$ is given by $d \log \theta / d \log m = (\alpha + \beta\theta + \gamma\theta^2)/(\alpha + 2\beta\theta + 3\gamma\theta^2)$, a function rather insensitive to variation in $\theta$ because of the relative magnitudes of $\alpha$, $\beta$ and $\gamma$. This small variation is illustrated well by ideal benzene solutions, for which $m = 0{\cdot}1953\theta + 2{\cdot}4 \times 10^{-3}\theta^2 + 1{\cdot}4 \times 10^{-5}\theta^3$. This leads to values of $b$ varying from 1 to 0·945 for concentrations from 0 to 1 molal respectively. Non-ideal solutions can be represented in a similar form with different coefficients and slightly smaller values of $b$. Such variations in slope would be barely noticeable in a logarithmic plot of the empirical relation, and most certainly tend to be masked by experimental variation in $\theta$.

There remains to discuss the experimentally observed decrease in $\theta/m$ with increasing concentration. Many of the reported anomalies in the literature can doubtless be attributed to the use of the van't Hoff limiting constant at finite concentrations. Rigid calculation shows that, for ideal benzene solutions, we must expect $\theta/m$ to change from 5·122 at $m = 0$ to 4·81 at $m = 1{\cdot}0$ molal. The effect of applying the limiting constant to ideal solutions of a substance of formula weight 100 would be to give an apparent value of 107·5 at 1 molal. For non-ideal solutions such variations will be even larger.

The data given for solutions of tetralin in benzene[1] show anomalies which are too large to be so explained.

1. Low concentrations give $\theta/m$ already in excess of the accepted limiting value 5·122, a value expected from thermal data and corroborated by the careful and extensive measurements of Bury and Jenkins[2] on the freezing points of numerous benzene solutions.

2. The molecular weight of tetralin found is 136 instead of 132·2 which its formula requires.

These abnormalities are removed if one assumes that insufficient precaution was taken to prevent access of moisture to the benzene during the measurement. Assuming these solutions to be saturated with water (0·0335 per cent at 5·4° C.)[3], then approximately the observed depressions are too high by 0·120° C. Making this correction gives the values $\theta/m$ in column 4 (below). Excluding the value at the lowest concentration, which appears to be in error, $\theta/m$ now shows a variation with concentration which is quite close to the values calculated for an ideal solution and shown in column 5.

The data extrapolate to $\theta/m = 5{\cdot}1$. Assuming

this value, molecular weights so calculated are given in column 6. These show a small variation with concentration, which extrapolates to a value lying between 132 and 133.

| Tetralin (molal) | $\theta$ corr. | $(\theta/m)$ uncorr. | $(\theta/m)$ corr. | $(\theta/m)$ calc. | $M$ |
|---|---|---|---|---|---|
| 0·8422 | 4·196 | 5·120 | 4·982 | 4·86 | 135·2 |
| 0·6008 | 3·045 | 5·267 | 5·069 | 4·93 | 132·9 |
| 0·3008 | 1·516 | 5·441 | 5·040 | 5·03 | 133·9 |
| 0·1495 | 0·756 | 5·359 | 5·056 | 5·07 | 133·6 |
| 0·0518 | (0·201) | (6·197) | (3·880) | — | (172·6) |
| | Extrapolated | | 5·1 | 5·12 | 132–133 |

The abnormal data for camphor given by Meldrum, Saxer and Jones[4] can also be explained by assuming the presence of some impurity. This is the explanation offered by Ricci[5]. Another possible source of error is the loss of camphor by sublimation during measurement.

W. H. BANKS.

Hampton,
Middlesex.

[1] *Nature*, **153**, 407 (1944).
[2] *J. Chem. Soc.*, 688 (1934).
[3] "Int. Crit. Tables", **3**, 389.
[4] *J. Amer. Chem. Soc.*, **65**, 2023 (1943).
[5] *J. Amer. Chem. Soc.*, **66**, 658 (1944).

THE exact equation for an ideal solution has the form

$$d \log x/dt = \frac{\Delta H}{RT^2}, \quad . \quad . \quad . \quad . \quad . \quad . \quad (1)$$

where $x$ is the mol. fraction of the solvent and $\Delta H$ is the molar latent heat of fusion.

It can be shown that the classical equation

$$\theta = Km \quad . \quad . \quad . \quad . \quad . \quad . \quad (2)$$

where $m$ is the molality results from two main approximations applied in the reduction of (1) to (2), and it has been assumed in the literature that the variation in $\theta/m$ found with (2) is due to these approximations.

Banks has now shown that $\theta/m$ still varies even when an accurate expression derived from (1) is obtained, namely,

$$m = \alpha\theta + \beta^1\theta^2 + \gamma^1\theta^3 \quad . \quad . \quad . \quad . \quad (3)$$

Using equation 2, $K$ found experimentally falls from an abnormally high value at $m = 0$, approaching the thermodynamic figure at $m = 1$.

Equation 3 likewise shows a fall in the value of $\theta/m$, but in this case $K$ is defined at $m = 0$. Because of the difficulty in obtaining experimental data at low concentrations and therefore extrapolating to infinite dilution, we evolved the empirically deduced equation:

$$\theta = Km^b \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (4)$$

For the ideal case studied by Banks, $b$ has been found to vary, but as he has pointed out, the order of this variation is such as to be masked by experimental error. From the practical point of view, therefore, this variation must be insignificant.

If, as it has been suggested, the abnormal results of Meldrum, Saxer and Jones were due to sublimation or impurities in the camphor, then we should have to accept the untenable conclusion that in our confirmatory work on camphor the same amount of sublimation and the same unspecified impurities were present. Further, the experimental results on which equation (4) is based have been checked by plotting $\log x$ against $1/T$, and the slopes of the lines obtained at any point gave latent heats of fusion of the solvents in close agreement with the literature values.

Finally, we have applied the moisture correction of 0·120° C. to the tetralin results; also to solutions of naphthalene in a different sample of benzene:

Tetralin: $b = 0·9394$

| Concentration (gm. per 100 gm. solvent) | Molality | $\theta$ | $\theta$ corrected | $\theta$ corr./$m$ | $\frac{\theta}{m^b}$ |
|---|---|---|---|---|---|
| 0·685 | 0·0518 | 0·321 | 0·201 | 3·880 | 5·180 |
| 1·977 | 0·1495 | 0·876 | 0·756 | 5·056 | 5·220 |
| 3·976 | 0·3008 | 1·636 | 1·516 | 5·040 | 5·169 |
| 7·942 | 0·6008 | 3·165 | 3·045 | 5·069 | 5·107 |
| 11·134 | 0·8422 | 4·316 | 4·196 | 4·982 | 5·072 |

Naphthalene: $b = 0·9846$

| Concentration (gm. per 100 gm. solvent) | Molality | $\theta$ | $\theta$ corrected | $\theta$ corr./$m$ | $\frac{\theta}{m^b}$ |
|---|---|---|---|---|---|
| 0·653 | 0·0510 | 0·279 | 0·159 | 3·118 | 5·225 |
| 0·922 | 0·0720 | 0·390 | 0·270 | 3·750 | 5·201 |
| 1·126 | 0·0880 | 0·477 | 0·357 | 4·058 | 5·223 |
| 3·430 | 0·2680 | 1·452 | 1·332 | 4·970 | 5·310 |
| 7·181 | 0·5610 | 2·922 | 2·802 | 4·995 | 5·162 |
| 10·160 | 0·7938 | 4·162 | 4·042 | 5·092 | 5·225 |

If the moisture correction were valid and could be accepted as the explanation of the anomaly found by using (2), then the results given in column 5 of the above table should extrapolate to 5·12 at $m = 0$.

In view, however, of the results obtained with naphthalene, we cannot conclude that the water correction can be used as an explanation of the anomaly. The values of $\theta/m^b$, however, approximate to a constant value for $K$, which we believe can be used in actual determinations of molecular weights.

## Commutation of Annual Subscriptions

DR. HERON's letter in *Nature* of September 23 should be of special interest to British scientific men, in that commutation gets over the legal anomaly that subscriptions to technical societies are not chargeable as expenses for the purposes of income tax, unless the taxpayer is working on his own. Those paid by salary cannot enter subscriptions as an expense, even when appointment is conditional on membership of some appropriate technical institution.

The difficulty is eliminated because commutation is equivalent to buying an annuity for the amount of the annual subscription, without the member becoming liable to tax on the capital part of the annuity; and also to tax on the income part, if the body happens to come within the rather artificial legal definition of a charity, and most technical ones do so. With non-charitable bodies commutation fees should necessarily be higher, in that tax has to be paid on the income from the commutation fund.

The fact is that it almost always pays for good lives to commute, even when the purpose is not to avoid income tax; for there is a general tendency to fix commutation fees too low, even in relation to the current annual subscription. Actually the fees should make some provision for the possibility of future rise in annual subscription, necessitated not only on account of the tendency for the value of money to fall in the course of years, but also by the desire of any active institution to widen the scope of its activities, for the general benefit of its members.

# RODS AND CONES, AND THOMAS YOUNG'S THEORY OF COLOUR VISION

By Dr. M. H. PIRENNE
Psychological Laboratory, Cambridge

MR. E. N. WILLMER'S recent communications[1,2] on the physiology of colour vision once more direct attention to the essential principles involved in Thomas Young's theory. As is well known, it is on purely logical grounds that Young in 1801 came to the conclusion that the existence of three kinds of receptors having different spectral sensitivities—as we would say to-day—should account for the facts of normal colour vision[3]. At the basis of the theory lies[4] the principle of the 'specific energy of nerves', formulated by J. Müller[5] in 1840, according to which each nerve fibre can send only one kind of sensory message to the brain. This would seem to lead to the conclusion that there must be as many different kinds of receptors as there are colours; but Young's well-known hypothesis allows this number to be reduced to three. For the abnormal colour vision of such persons as his contemporary Dalton, Young himself suggested as an explanation "the absence or paralysis of those fibres of the retina which are calculated to perceive red"[6]; that is, dichromats would possess only two colour receptors instead of three. To-day the strength of this theoretical argument referring to the whole retina remains undiminished[7,8,9,10].

Meanwhile, however, as the properties of the actual retinal receptors became better known, the duplicity theory was evolved. According to it, the rods mediate only a colourless kind of vision, while colour vision is entirely mediated by the cones[11]. If this is the case, then Young's reasoning must be applied to the cones, leading to the conclusion that there are three different kinds of cones. Now, however, Mr. Willmer[1,2] has made the radically different suggestion that the rods constitute one of the kinds of receptors which mediate colour vision. It seemed advisable, therefore, to make some new experiments on the response to coloured lights of rod-free and rod-containing regions of the retina when the eye is completely dark-adapted, that is, when the sensitivity of the rods is greatest.

Two observers whose colour vision is normal according to the Ishihara test were used. The observer's right eye viewed a small red fixation point through a 2 mm. artificial pupil. The test field, the diameter of which subtended an angle of 10′ at the eye, was constituted by the surface of an opal electric bulb seen through a small circular opening. It was exposed in flashes of 0·04 sec. It could be presented at various distances from the fixation point on the horizontal meridian. Violet light was obtained using Corning filter 511, which transmits only below 470 mμ; red light, using Wratten filter 88, which transmits only beyond 700 mμ. The light intensity could be changed by using a system of two neutral wedges calibrated for these lights. The brightness of the test field was calculated from the colour temperature of the light source, the spectral transmission of the filters, the I.C.I. photopic visibility curve and the brightness of the opal bulb. The latter brightness is not very accurately known, but this is of little importance here, for the error would affect all threshold values by the same amount. Using this arrangement, the absolute threshold (brightness at which the stimulus is seen with a 50 per cent frequency) was determined in various regions of the dark-adapted fovea and parafovea.

Fig. 1 shows the results of a typical experiment. For violet light, the threshold decreases slightly as the angular distance between test field and fixation point increases from 0·15° to 0·75°. Then it drops suddenly and at 3·75° it is about 2 log units lower than near the centre of the fovea. At angles up to 0·75°, both observers reported that the field, when seen at all, appeared of a deep violet or blue colour; at the higher angles it always appeared colourless. For red light the threshold value changes little with the angle, being slightly higher at higher angles. When it was seen, the test field always appeared red. In the central region, the present results differ from those of Wentworth[12] who, using a larger test field (1° 16′ in diameter), found an achromatic threshold lower than the chromatic threshold. The present results for extreme red are similar to those of Mandelbaum[13].

Fig. 2 reproduces the distribution of rods and cones in a human retina studied by Østerberg[14]. The central region contains only cones, the first rods appearing at an angle of about 0·34°. The number of rods per unit area goes on increasing while the number of cones decreases, the two numbers being

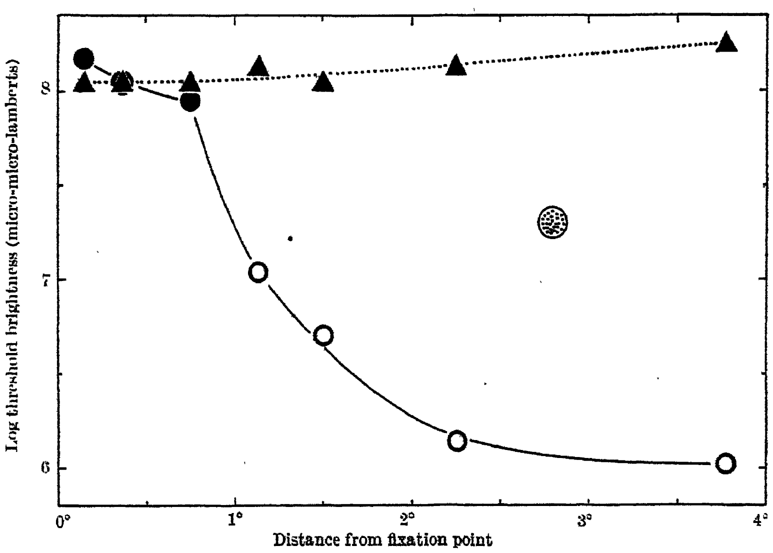

Fig. 1. THRESHOLD VALUES FOR EXTREME BLUE (SMALL CIRCLES) AND EXTREME RED LIGHT (TRIANGLES) IN VARIOUS PARTS OF THE RETINA, TEMPORALLY TO THE FIXATION POINT.

The full circles and triangles correspond to coloured vision; the open circles to colourless vision. The large dotted circle represents the dimensions of the test field.

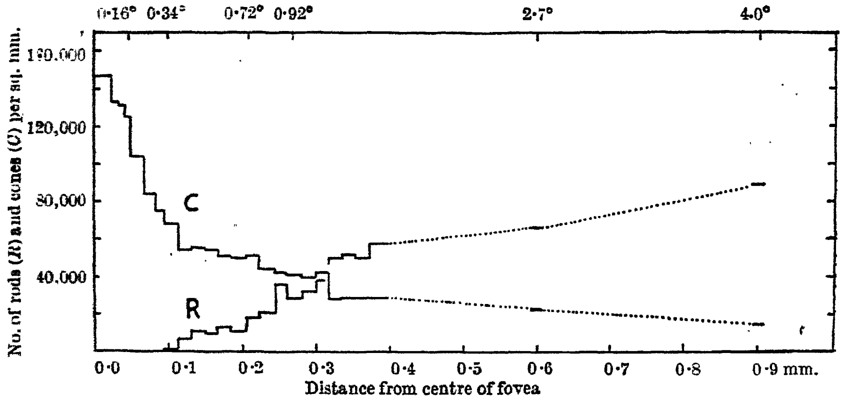

Fig. 2. DISTRIBUTION OF RODS AND CONES IN THE CENTRAL PART OF A HUMAN RETINA, FROM THE DATA OF ØSTERBERG[14].

The distances in mm. are uncorrected for shrinkage of the preparation (multiply by 1·31 to obtain the real distances). The corresponding distances in perimetric degrees have been calculated by Østerberg.

Perfect correspondence between Figs. 1 and 2, of course, cannot be assumed, since they refer to different eyes.

equal at an angle of about 1°. Comparison of Figs. 1 and 2 clearly shows that, for violet light, the threshold is high and the light is seen coloured in the rod-free area, while the threshold is much lower and the light appears colourless in the area where the rods are considerably more numerous than the cones, that is, at angles larger than 2°. In the intermediate region, the passage from coloured to colourless vision occurs only at an angle where the rods are fairly numerous, as might have been expected. For red light, the presence or absence of rods has little influence on the value of the threshold or on the colour of the light in the region studied here (at an angle of 7·5°, however, the light appeared orange).

These results are in full agreement with the duplicity theory[11,15,16]. With regard to the special problem of colour vision, it can be concluded that, under the present conditions, the rod-free area of the fovea is the best region for colour vision. The rods are not necessary for colour vision: on the contrary, where they are present in fair numbers, the colour of the violet test field vanishes.

It might be objected, however, that the colour vision mediated by the central rod-free area under these conditions may not be the same as normal colour vision in the light-adapted eye, and perhaps has not the properties to be expected from a three-receptor system. That this region contains at least two kinds of receptors is shown by the fact that red and blue are clearly differentiated: for, if it contained only one kind of receptors, there could be no wave-length discrimination at all. But it has been suggested[2] that it might contain only two kinds of receptors. In that case, using small fields falling inside the rod-free area, it should be possible to match any wave-length or mixture of wave-lengths with mixtures of red and blue in suitable proportion. I tried to test this, using an improvised apparatus, but no definite results were obtained. It was found that some red-blue mixtures become difficult to differentiate from yellow, but it was not certain whether the hues of the two test fields really became indistinguishable. Hue discrimination becomes poor when the test fields are small[17]. This well-known effect, and the imperfections of the apparatus, may or may not account entirely for the fact that at times a match appeared to be obtained. Experiments with a good colour-mixing apparatus are needed to settle this question.

As the assumption that there are only two kinds of receptors leads to conclusions at variance with the facts of normal colour vision, Young's theory asserts that at least three kinds of receptors—whatever they may be—must exist. On the other hand, the conclusions derived from the two-receptor assumption are in agreement with the observations made on dichromats. This provides a more positive kind of evidence in favour of the theory, and this evidence is perhaps more complete than is generally supposed. As is well recognized, if there are only two kinds of receptors there must be one wave-length—the neutral point in the spectrum of the dichromats—which stimulates the two receptors precisely in the same ratio as composite white light does. Now, on the short wave-length side of this neutral point, the stimulation by any wave-length must be the same as that by white light plus, say, 440 mμ; on the other side of the neutral point, by white plus, say, 650 mμ. In either of these parts of the spectrum, therefore, saturation changes must be the sole basis for wave-length discrimination and colour matching. This is precisely what has been found in a relatively recent investigation of the vision of dichromats[18]. The same situation should also be expected to exist in the rod-free area of normal subjects if this area is really a two-receptor system.

I am indebted to Prof. F. C. Bartlett for the hospitality he gave me in his laboratory. The experiments reported here were made in January and March 1944, with Mr. Willmer, whom I wish to thank for acting as a subject. The apparatus which was used is the property of the Medical Research Council.

# STATUS OF PROFESSIONAL CIVIL SERVANTS

THE recommendations of the Emergency Executive Committee of the Institution of Professional Civil Servants, which it is claimed represents more than 30,000 members of all grades and classes of the professional, scientific and technical staffs of the Civil Service, for the post-war reconstruction of the technical Civil Service, are summarized in a pamphlet recently issued by the Institution (Pp. 4). Broadly, the proposals aim at common salary scales for all professional classes, and a high standard of recruitment and service conditions which will attract to the service of the State the best brains in Great Britain. Within the membership of the Institution there are more than five hundred grades, and the Institution takes the view that the calibre of the officer should be the touchstone in deciding remuneration and that there is no reason why fully qualified scientific workers, engineers, architects, surveyors, etc., should not be paid on common scales. The education of the fully qualified professional man has been such that it produces a man at least equivalent in calibre to the normal entrant to the administrative class, and accordingly the remuneration of the fully qualified technician or scientific man should be on a parity with that of the administrative class. It is proposed that there should be three classes in the Service, each class being normally divided into two grades. Above this basic structure there should be directing posts, the salaries of which would be fixed according to the responsibility of the post. The three classes are designated principal class, executive class, and ancillary class.

Recruitment to the principal class should be from those possessing full professional, scientific or technical qualifications, such as a first or second class honours degree in the relevant science, or membership of the appropriate technical institution. The two grades within this class would be assistant principal and principal, appropriately amplified by fuller titles for different branches of work (for example, assistant principal engineer, principal scientific officer); and the grades should carry parity in remuneration with the assistant principals and principals of the administrative class (at present £275–£625 and £800–£1,100 a year). The members of the executive class would generally work under the direction of members of the principal class and undertake normal technical duties, as well as supervisory duties in workshops and laboratories where full professional qualifications are not required. Recruitment would normally be at the age of eighteen to nineteen years from persons with a good standard of secondary education. The two grades within the class should have parity of remuneration with non-technical executive officers (at present £150–£525) and staff officers and senior staff officers (at present £550–£750). In both these classes the maximum of principal or executive officer should normally be reached well before retiring age.

The third, the ancillary class, would be responsible for routine duties for which it would not be appropriate to employ members of the executive class. It would be roughly comparable with the present clerical class, the standard of education of which is the general schools examination or matriculation. The greatest care should be exercised in the employment of young persons in the ancillary class. Those who show special ability should be afforded an opportunity of acquiring training which would qualify them for entry into the executive class, and this training should not involve undue evening work.

With regard to recruitment, central recruitment should replace recruitment on a purely departmental basis, with a central recruiting board for technical posts under the ægis of the Civil Service Commissioners, and composed of persons with wide experience of professional, scientific and technical staffing requirements. This board's duty would be to certify as eligible for posts in the Civil Service candidates whose qualifications fulfilled agreed standards. It should have the fullest co-operation of the universities and professional institutions, but actual appointments would be made by departmental or regional boards from among those selected by the central board. Since all staff would be recruited by the Civil Service Commissioners, they should be treated on the same basis as the non-technical Civil servants, and come under whatever superannuation scheme is agreed for the Civil Service as from their date of entry into the Service, instead of having to wait several years to qualify for pension rights as have the majority of technical staffs at present.

The reasons for these proposals, which the Institution believes would greatly strengthen the technical service of the State and enable it to play its full part in the post-war reconstruction of Great Britain, are set forth in fuller detail in a second statement prepared on the instructions of the Emergency Executive Committee (Pp. 16. 6*d*.). Some of the recommendations, it is emphasized, are the considered views of that Committee; others are first thoughts, but all are capable of revision in the light of discussion among the membership. A brief report of the Conference on Post-War Reconstruction, held on March 4 and 5, when the draft proposals were considered is included.

Discussing the scope of the recommendations, the statement, recognizing that the professional, scientific and technical branches of the Civil Service need a drastic overhaul, urges that it is essential that this side of the Service should play its part in shaping the post-war Civil Service as a whole, and that the whole Service will be intimately associated with the people in a way which would have seemed impossible before rationing, controls and the inescapable need for central direction of the national economy shattered the aloofness of the servants of the State. As the extent of the contribution of Civil servants to social welfare increases, they must ensure that their tasks are carried out with initiative, flexibility and a full understanding of their implications and repercussions.

In a brief survey of the functions of the professional, scientific and technical staffs, the statement quotes recent evidence that the importance of those functions is becoming more widely recognized, and refers to the approach of the Anderson Committee and the Tomlins Commission to the problem of simplification of the structure of this branch of the Civil Service. It notes that provision must be made for recruitment at higher age-levels to the principal class to obtain the benefit of experience outside the Service, and emphasizes that the duty of the central recruiting board should be limited to certifying the eligibility of candidates for appointment to the Civil Service, selections being made by the departmental or regional boards on the basis of interviews.

A section of the statement deals with the special problems of the immediate future, such as priority

for permanent posts, redundancy, and recruitment at the termination of hostilities. The statement also emphasizes the desirability of the Appointments Department of the Ministry of Labour remaining in being after this transition period and not only registering the qualifications of professional, scientific and technical personnel, but also keeping a register of posts occupied by them, including at least the scale of remuneration of the post. The Institution's support of equal pay for men and women and opposition to the marriage bar is re-affirmed. Consideration of the possibility of the Civil Service Commission adding to its functions in order to become a body for determining salaries is suggested, and an endeavour is proposed to restore the true functions of the Whitley Councils, which include the utilization of the experience of the staff in planning the work of the departments.

## FORTHCOMING EVENTS

*(Meeting marked with an asterisk * is open to the public)*

### Monday, December 11

ROYAL ANTHROPOLOGICAL INSTITUTE (joint meeting with the ENGLISH FOLK DANCE AND SONG SOCIETY) (at Cecil Sharp House, 2 Regent's Park Road, London, N.W.1), at 6.30 p.m.—Dr. Ethel John Lindgren: "Shamanism—Some Manifestations in Manchuria".

### Tuesday, December 12

CHADWICK LECTURE (at the Royal Society of Tropical Medicine and Hygiene, 26 Portland Place, London, W.1), at 2.30 p.m.—Dr. George H. Walker: "Food and its Adulteration during the Present War".*

CHEMICAL ENGINEERING GROUP (joint meeting with the INSTITUTION OF CHEMICAL ENGINEERS) (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 2.30 p.m.—Mr. Norman Clarke Jones: "Forestry, and the Utilisation of Waste Wood and its Products as Fuel".

ROYAL INSTITUTION (at 21 Albemarle Street, Piccadilly, London, W.1), at 5.15 p.m.—Sir Henry Dale, O.M., G.B.E., Pres.R.S.: "Modern Developments in Chemical Therapeutics", (ii) "Recent Advances in Chemotherapy".

### Tuesday, December 12—Wednesday, December 13

AGRICULTURAL EDUCATION ASSOCIATION (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1).—Yearly Conference.

**Tuesday, December 12**

At 9.30 a.m. (County Education Section)—Mr. F. H. Garner: "The Growing of Field Beans"; Dr. W. A. R. Dillon Weston: "The Fungus Diseases of Field Beans".

At 10 a.m. (Biology Section)—Discussion on "Modern Methods of Pasture Evaluation" (to be opened by Messrs. William Davies and J. Lambert).

At 10.15 a.m. (Analysis of Fodders Sub-Committee)—Discussion on the Report on "The Sampling of Baled Dried Grass for Chemical Analysis".

At 11 a.m. (Dairying Section)—Mr. E. L. Crossley: "Dried Milk Production in War-time".

At 11.15 a.m. (Agriculture Section)—Dr. T. Wallace: "Some Aspects of Mineral Deficiencies in Farm Crops"; Mr. V. C. Fishwick: "The Influence of Nutrition during Early Life on Breeding Capacity and Milk Production".

At 11.15 a.m. (Chemistry Section)—Mr. F. Knowles: "Notes on the Poisoning of Plants by Zinc".

At 2.30 p.m. (First Paper Reading Session)—Dr. C. Crowther: "Agricultural Education and the Work of the A.E.A., 1894–1944"; Mr. James Mackintosh: "Fifty Years of Dairying in Great Britain".

**Wednesday, December 13**

At 10 a.m. (Second Paper Reading Session)—Prof. R. G. White: "The Live Stock Industry in Britain during the last Fifty Years".

### Wednesday, December 13

INSTITUTE OF FUEL (at the Institution of Mechanical Engineers, Storey's Gate, St. James's Park, London, S.W.1), at 2.30 p.m.—Mr. N. S. Billington: "The Insulation of Buildings—Domestic and Industrial".

INSTITUTE OF PETROLEUM (at 26 Portland Place, London, W.1), at 4.30 p.m.—Prof. V. C. Illing: "Exploration".

INSTITUTION OF ELECTRICAL ENGINEERS (TRANSMISSION SECTION) (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Mr. W. Szwander: "Valuation and Capitalization of Transformer Losses".

BRITISH INSTITUTION OF RADIO ENGINEERS (at the Neville Hall, Westgate Road, Newcastle-upon-Tyne), at 6 p.m.—Dr. T. H. Turney: "Wave Guides".

### Thursday, December 14

GENETICAL SOCIETY (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 2 p.m.—Mr. D. G. Catcheside: "Nature of Lethals in *Drosophila melanogaster*", 1: "Experimental"; Mr. D. E. Lea: "Nature of Lethals in *Drosophila melanogaster*", 2: "Theoretical"; Dr. G. Pontecorvo: "Genetic Aspects of Heterokaryosis"; Prof. J. B. S. Haldane, F.R.S., and Mr. H. L. K. Whitehouse: "Meiosis in some *Ascomycetes*"; Mr. A. Haddow: "The Artificial Induction of Coat Coloration in Albino Rats"; Mr. P. T. Thomas: "Experiments Imitating Tumour Development"; Mr. U. Philip and Mr. A. Sorsby: "Mutation-rate of Retinoblastoma in Man".

ROYAL INSTITUTION (at 21 Albemarle Street, Piccadilly, London, W.1), at 2.30 p.m.—Prof. James Gray, F.R.S.: "Locomotory Mechanisms in Vertebrate Animals", (iv) "Relationship of Limb Form to Habit and Environment—Evolution of Types for Climbing and Running".

INSTITUTE OF FUEL (YORKSHIRE SECTION) (at the Chemistry Lecture Theatre, The University, Leeds), at 3 p.m.—Mr. D. W. Milner and Mr. E. Brett Davies: "Coal Tar and its Products as Fuel, and in the Chemical Field".

INSTITUTE OF PETROLEUM (joint meeting with the ROAD AND BUILDING MATERIALS GROUP OF THE SOCIETY OF CHEMICAL INDUSTRY) (at 1 Grosvenor Place, London, S.W.1), at 4 p.m.—Mr. P. Alexander and Mr. J. F. T. Blott: "Factors Influencing the Structural Stability of Sand Carpets".

INSTITUTION OF ELECTRICAL ENGINEERS (INSTALLATIONS SECTION) (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Mr. J. C. B. Nicol: "Organization of Industrial Electrical Maintenance".

PHARMACEUTICAL SOCIETY (at 17 Bloomsbury Square, London, W.C.1), at 7 p.m.—Dr. G. W. Scott-Blair: "Rheology and the Pharmacist".

BRITISH INSTITUTE OF RADIOLOGY (in the Reid-Knox Hall, 32 Welbeck Street, London, W.1), at 8 p.m.—Mr. A. Craig Mooney: "Disc Lesions in relation to Pain"; Mr. Hugh Davies: "The Symptomatology and Radiology of Cervical Intervertebral Discs".

### Friday, December 15

SOCIETY OF CHEMICAL INDUSTRY (PLASTICS GROUP) (at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 2.30 p.m.—Dr. R. R. Smith: "Kinetics of Vinyl Polymerisations in the Liquid Phase".

ROYAL INSTITUTION (at 21 Albemarle Street, Piccadilly, London, W.1), at 5 p.m.—Dr. L. R. G. Treloar: "Rubbers and their Characteristics, Real and Ideal".

INSTITUTION OF MECHANICAL ENGINEERS (at Storey's Gate, St. James's Park, London, S.W.1), at 5.30 p.m.—Mr. E. J. Heeley: "Some Considerations in the Design of Class 1 Pressure Vessels"; Dr. S. F. Dorey: "A Note on Design Stresses in Class 1 Pressure Vessels".

NORTH-EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS (in the Lecture Theatre of the Literary and Philosophical Society, Newcastle-upon-Tyne), at 6 p.m.—Prof. C. E. Inglis, F.R.S.: "The Determination of Critical Speeds, Natural Frequencies and Modes of Vibrations by Means of Basic Functions" (Parsons Memorial Lecture).

### Saturday, December 16

PATHOLOGICAL SOCIETY OF GREAT BRITAIN AND IRELAND (joint meeting with the BIOCHEMICAL SOCIETY) (at the Royal Society of Medicine, 1 Wimpole Street, London, W.1), at 11 a.m.—Discussion on "Cancer".

QUEKETT MICROSCOPICAL SOCIETY (at the Royal Society, Burlington House, Piccadilly, London, W.1), at 2.30 p.m.—Dr. W. S. Bristowe: "In Quest of Spiders".

## APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

GRADUATE LECTURER IN BIOLOGY, with qualifications in Anatomy and Physiology, in the Mining and Technical College, Crumlin—The Director of Education, Higher Education Department, County Hall, Newport, Mon. (December 13).

AGRICULTURAL TRAINING OFFICER (administrative)—The Executive Officer, Leicestershire War Agricultural Executive Committee, 7 Friar Lane, Leicester (December 16).

ASSISTANTS (2), one in the MECHANICAL and one in the ELECTRICAL ENGINEERING DEPARTMENT—The Principal and Secretary, Harris Institute, Preston (December 18).

ANALYST by an Engineering Establishment in Lancashire (works experience in the analysis of ferrous and non-ferrous metals and alloys essential)—The Ministry of Labour and National Service, Central (T. and S.) Register, Room 5/17, Sardinia Street, Kingsway, London, W.C.2 (quoting Reference No. F.1169.XA) (December 19).

LABORATORY ASSISTANT (Grade I) IN THE DEPARTMENT OF BOTANY—The Secretary, Bedford College for Women, Regent's Park, London, N.W.1.

YOUNG ENGINEER OR PHYSICIST with good mathematical qualifications, for development work on Turbines—The Manager, Employment Exchange, Warwick Road, Wallsend.

TECHNICAL ASSISTANT IN THE EDINBURGH ELECTRICITY DEPARTMENT—The Engineer and Manager, 1 Dewar Place, Edinburgh 3.

DIRECTOR of a comprehensive scheme for Recruitment, Training and Education of personnel of all grades in all Coalfields of the country—The Chairman, Mining Association of Great Britain, 53 Parliament Street, London, S.W.1.

LABORATORY ASSISTANT IN THE DEPARTMENT OF BOTANY—The Bursar and Acting Registrar, University College of North Wales, Bangor.

## FUNCTION OF CONTROLS IN INDUSTRY

THE eighth report of the Select Committee on National Expenditure for the session 1943–44 arose out of an inquiry into the chemical controls of the Ministry of Supply, and should remove certain widespread misapprehensions by making plain their functions and responsibilities. Although primarily concerned with the chemical controls, since these are only a part of the organization of the Ministry of Supply for dealing with the chemical industry, the inquiry could not be confined strictly to the activities for which the controllers and their staffs are responsible: In addition to the evidence of the controllers themselves and of the chairman of the Chemical Control Board, evidence was heard from the Ministry of Supply, including the Raw Materials Department and the Director-General of Scientific Research and Development, and the Ministry of Aircraft Production, including the Director-General of Materials Production and the Deputy Director of Research and Development (Technical Investigations). Memoranda were also submitted by trade associations and their firms. The report is accordingly a useful contribution to the present debate on the organization and control of post-war industry.

There are five chemical 'controls', dealing respectively with sulphuric acid, fertilizers, industrial ammonia, molasses and industrial alcohol, and plastics; the control of miscellaneous chemicals has recently been taken over by the headquarters of the Raw Materials Department of the Ministry of Supply. The controls thus form a group within the twenty-nine raw material controls administered by the Ministry, the five controllers constituting a board presided over by a chairman who is responsible for co-ordinating their activities. Describing first the responsibilities and functions of the controls, the report points out that in principle they are executive. The ultimate responsibility for the supply of essential raw materials lies with the Raw Materials Department of the Ministry of Supply; but the controls are the source of information and advice about the complex industries with which that Department has to deal. They thus perform an important advisory function in what may be called the semi-technical field of trade and industry. They are concerned with every kind of action which the Department may be required to take to ensure supplies and their proper distribution and use. In addition to a general supervision of the trade or industry with which it deals, a control may initiate arrangements for the import of supplies from abroad, the provision of new capacity in Great Britain, the distribution of material to the manufacturers or users, and the rationing of supplies to manufacturers and users; and it directs the purposes for which materials may be used and fixes the price of materials.

The importance of utilizing, in the administration of the controls, the knowledge and experience of the trades and industries concerned, has led to the appointment of staff mainly formerly employed in

the relevant businesses, and the report details the over-riding principles which have been laid down to safeguard the public interest in making such appointments. There is no suggestion in the report that these safeguards have not proved adequate; but the report emphasizes that the advisory and information services should be a two-way function; in particular, in referring to the use of existing capacity, the Committee points to the need for giving more adequate explanation to manufacturers whose capacity cannot, for one reason or another, be fully employed. This is a particular illustration of the importance of the advisory committees of manufacturers and others which in some sections of the chemical industry, notably in the fertilizer industry, assist the control to settle both the programme and the way to execute it. So long as the controls remain it is of the utmost importance that they should retain the confidence of the industry, and the existence of an active advisory committee is an excellent means to that end. None the less, in view of the easing of the supply position and the decrease in work, the Committee recommends that the whole organization of the chemical controls should be reviewed and consideration given to the advantages of absorbing them into the headquarters of the Raw Materials Department.

While much of the criticism of the controls is attributed to ignorance of their true position, specific allegations regarding their operation relate to the use of existing capacity, the distribution of new capacity to firms, the allocation of contracts for research and development, and the concentration of production in the paint industry. With regard to the first, the Committee considers that furnishing more adequate explanations and using advisory committees, as already indicated, would have removed its substance. In regard to the second and third points, and particularly the development of methyl methacrylate sheeting or 'Perspex', the Select Committee queries the mode of following the usual policy and giving the whole of the additional capacity for making 'Perspex' to the one original manufacturer. The report suggests that progress might have been more rapid if other firms with the necessary technical facilities had been brought in. A fresh approach to the problems might have resulted in greater progress towards a satisfactory solution.

On the whole, the operation of the chemical controls has tended to strengthen rather than diminish the preponderance of the strongest interests in the chemical industry. This tendency, the Committee recognizes, may be to some extent inevitable in time of war, but in spite of the immense value to the national effort of the resources of the interests in question, there is danger that too much reliance may be placed on the strength of a single concern, making, for example, the control of costs by the Department difficult, since there is no standard of comparison and overheads are difficult to calculate.

Some concern is also expressed by the Committee whether considerable facilities for research and development have been neglected. It is pointed out that even if a firm should not have full confidence in the integrity of the technical officers of the controls, this suspicious attitude should not necessarily prevent the acquisition of the information about its facilities for research and development required before a contract can be allotted. There are Government institutions, such as the Department of Scientific and Industrial Research, the permanent position of which in the service of the State places their impartiality above suspicion, and precedents exist for the use of these bodies where a firm is disinclined to disclose information to the officers of a Department.

The most serious criticism of the report, however, is that of the treatment of the paint industry, and the Select Committee considers that the system of lists adopted was neither economical nor fair. If it was considered that redundant paint-making capacity should be closed, there should have been a proper scheme as provided in the White Paper on concentration of production, with safeguards for the preservation of the commercial existence of closed firms and for compensation. Abandonment forthwith of the lists prepared by the Miscellaneous Chemical Control of paint firms where labour is protected, and to which Government departments confine their direct orders, is recommended.

The report thus affords some justification for the general criticism of the whole system of controls advanced by G. D. N. Worswick in "The Raw Material Controls" (Fabian Tract Series, No. 257. 4*d*.). Mr. Worswick traces the weaknesses of the controls, particularly in planning and lack of foresight, to the staffing of the controls with those already fully conversant with the industry or trade concerned. He argues that the qualities required of a good controller are much the same as those required of a good Minister: intelligence, the ability to grasp quickly the nature of a problem, and the determination to carry out any policy that has been decided. The controller must, of course, have his advisory team of experts, industrial and technical; but what is above all essential in the controller is impartiality and independence of the traditional background of the particular industry and trade. Mr. Worswick argues further that the controls are an essential part of reconstruction, where they should form part of a new branch of government charged with the provision of all the principal industrial raw materials, and the production of substitutes if natural supplies are no longer available. For this purpose three principles are laid down for staffing the controls. First, the head of each control should have no past, present or probable future financial interest whatever in the material he is controlling. Secondly, the use of existing trade organizations as controls should be abolished altogether; and thirdly, the controller should be employed on a terminable contract, say, for five years. To secure the best men, Mr. Worswick suggests that it may be necessary to pay the controllers on the industrial rather than on the Civil Service scale.

In his emphasis on the question of staff and on policy, rather than on the exact nature of the organizational relation of government and industry, and even more on the ownership of industry, Mr. Worswick is

in line with the trend of a subsequent report by a Fabian Research Group "Government and Industry: A Framework for the Future" (Research Series, No. 83. Fabian Society. *6d.*), though he does not lay the same stress on intelligence and information service as the latter report and that of the Select Committee. That function, however, is as vital as the question of staffing and the direction of policy. Unless the Ministry responsible for the controls is well informed, it will not be able either to give guidance on principles of policy which will be commonly applied over the whole field of industry, agriculture and commerce, or indeed to decide on those principles and secure their application.

The review of the war-time controls in this Fabian Research Group report emphasizes that through the controls the Government has gained a far greater knowledge of industry than it had before. This in itself is a valuable asset in devising economic policy, and the reference in the White Paper on Employment Policy to the need for exact quantitative information about current economic movements suggests that the Government is unlikely to throw this away, whatever further means of supplementing it are required. The general supervision by the Government over most of the larger industries established in war-time has proved its value, and has indicated a means by which public policy can make itself felt in the fields of new investment, location of factories, research and development, labour management and labour policy and export policy, independent of the question of private or public ownership. The equity and desirability of such public control has been recognized in numerous statements in the last two years, such as that of Nuffield College on "Employment Policy and Organization of Industry after the War". Recent criticism of the Government has, in fact, centred on the failure of the Board of Trade to give the guidance which industry requires to make its concrete plans for serving the ends of both public and private policy.

The specific proposals of the Fabian pamphlet on "Government and Industry" are simple. A single central authority, specializing in such subjects as cartels, monopolies and restrictive practices, and the location of industry, and building up gradually a body of knowledge and technique, will be an indispensable part of the Government machine. Accordingly, in addition to a permanent buying Ministry to organize the whole of the Government's purchases from, and orders to, industry, there should be a central department for industrial control. This suggested department should be provided with expert sections to supervise all the great industries, whether fully nationalized or not, and should have a series of specialist bodies attached. Thus reinforced, the Board of Trade or Ministry of Industry would act as the final authority on the location of industry, the policy of monopolies and large-scale economic units, management, research and so forth. Again, while trade associations have legitimate functions to perform, they should not be allowed to exercise restrictive powers—a conclusion also reached by the Organization of Industry Committee of the Federation of British Industries in its recent report on the organization of industry in Britain. The Government must therefore have an organization separate from the trade association, through which to control the development of an industry, and to ensure that essential tasks, such as research, standardization, reorganization, export marketing and so forth, are adequately performed.

For this purpose, the Fabian Society's report proposes a series of development boards, not themselves trading bodies, but attached to individual industries and responsible to the section of the Board of Trade concerned with the industry in question. The scheme presupposes a central planning authority in the monetary and financial field, and the report recognizes that a good deal of industrial and managerial skill will be required. The system would make the fullest use of technical men and of business men, its success depending on the extent to which the appropriate administrative ability, impartiality and initiative, rather than technical knowledge, could be recruited. These, as Mr. Worswick stresses, are the ultimate safeguards against bureaucracy and the assurance of positive rather than negative control.

To the Fabian Society's Group, it is true, control still seems to be an end in itself. The committee recognizes the fruitful partnership between the State and industry which we have seen in our war-time arrangements at their best; and the admission that policy and quality of staff rather than sweeping changes in the present ownership of industry are what is required should make possible a broad range of agreement on the methods and objectives of any necessary measure of Government intervention and planning from the centre. The emphasis, however, must be on the minimum of control and on its positiveness in character, as in the Prime Minister's statement in the House of Commons on November 16. It is within these limits that we should seek to discover the principles that should guide and inspire the Government's intervention in industry and decide its policy.

The report of the Select Committee, like that of the Fabian Society's Group, should at least help to get the right questions asked. Few have done more, in fact, than Mr. Herbert Morrison, who contributes a preface to the Fabian report, to clear away prejudices and stimulate constructive thinking on these questions of the relations between industry and the State, and the form which industrial organization must take after the War. None the less, it must be admitted that the idea of restrictionism is embedded as deeply in reports and proposals from the Left, such as the interim report of the Trade Union Congress on post-war reconstruction, as in parallel statements from the industrial side, and it is this idea of restriction, from whichever side, that constitutes the greatest danger to what is commonly implied in a policy of full employment and freedom from want.

The Prime Minister's statement on the continuance of the controls shows that the Government is fully cognizant of what is required, and should reassure

those who, while recognizing the necessity for continuing control, are concerned lest control may be continued for its own sake. Given the principle that control will only be continued where and for so long as the public interest demands, it is possible to evolve out of our war-time and earlier experience the type and kind of control to suit our purposes. These purposes and needs will vary from industry to industry and with the national situation, but there is no reason to doubt the ability of Great Britain to develop a framework of government and industry sufficiently flexible to serve those needs and to foster enterprise and efficiency while securing the essential measure of public control. That involves, as Mr. Morrison and others have indicated, experimenting with different types and degrees of State control over industry, varying from public ownership and operation to a limited degree of control of prices and practices exercised from outside. It involves an intelligence service—or liaison or public relations service, call it what you will—adequate to ensure that the control is always in touch with the local or specialized needs of industries or communities. The joint production committees represent only one aspect of the way in which such public relations work must develop, and no section of a ministry to which the controls are entrusted is likely to be more important than its public relations department. Undoubtedly it will also involve special attention to the questions of recruitment and training of staff.

For all this, the war-time controls can provide only a part of the basic experience required. Beyond such experiment lie the vital factors of policy and of men, as so clearly indicated in the reports mentioned above.

Whatever machinery is devised, there must be the clear enunciation of policy at the centre. The execution of that policy must be entrusted to men who, whether drawn from the Civil Service or from industry, possess the administrative ability and initiative, the imagination and vision, and the impartiality and integrity to ensure that the nation's purposes are fully served.

## BIRDS AND THE CAMERA

### Birds of the Day

By Eric J. Hosking and Cyril W. Newberry. Pp. 128 (78 plates). (London and Glasgow: Wm. Collins, Sons and Co., Ltd., 1944.) 12*s*. 6*d*. net.

THERE is a well-known saying that great things arise from small beginnings, and this is true of modern bird photography, which began in those seemingly remote days when a stand camera was the only instrument for all types of photography. There is some dispute as to who took the first wild-life photographs. The names of Riley Fortune, Oliver Lodge and C. J. King, of the Scilly Isles, are among those of the pioneers. They worked with their heads under a black cloth, and their plates were so slow that they could only give a really fast exposure under exceptionally good lighting conditions. Yet they achieved some remarkable results, and when the Kearton brothers perfected the system of working from a hide, nature photography, and in particular the photography of birds, made rapid strides and attained wide popularity.

To-day those who practise bird photography and use their camera to record details of bird behaviour are beyond counting; but none of them has used his camera with better results than Mr. Eric Hosking, whose studies of birds are well known for their interest and beauty. Some of them are snapshots in the fullest sense of the word; for example, a picture in this, his latest book, of a marsh harrier alighting on its nest. The camera has caught it with wings raised in a pose as exquisite as that of a tern; while others are perfect portraits, models of exactness and of accurate rendering of every feather detail.

"Birds of the Day" is the joint work of Mr. Hosking and Mr. Cyril Newberry, the first named being responsible for the pictures of the forty or so species here dealt with, and the latter contributing much field work and descriptive matter. The descriptions vary from short paragraphs in the case of the blackbird and the song thrush to several pages in the case of the marsh harrier and the bittern, perhaps two of the most interesting birds found in Britain to-day. If this is termed a picture book we feel sure the authors will not cavil, for it is obvious the work of the pen is subsidiary to that of the camera.

The subjects are not treated in any special order or sequence, and are limited only to "Birds of the Day". Owls, we understand, are to be dealt with separately later on; however, an example of modern flashlight photography is given in this collection, namely, the portrait of a jackdaw at its nest in an old mill. The introduction of the soundless, odourless flash bulb has placed a most useful tool at the disposal of wild-life photographers. As examples of camera portraiture of birds the two very charming pictures of a male and female bearded tit, the latter with two dragonflies in her beak, perched on the reeds are indeed excellent, even if we long to see the cock depicted in all the beauty of his sandy-red and R.A.F. blue plumage, enhanced by the orange-yellow of his eye and beak, and set off by the black of his moustachial stripes. However, the extended use of colour photography in the ornithological field is coming fast.

For a useful record of bird-behaviour, combined with fine portraiture, the description of the greenshank carrying off hatched egg-shells from the nest and the accompanying illustration are particularly good. The authors tell us that a hiding tent had been in position beside the greenshank's nest for some days, but when the photographer arrived one morning he found the nest empty, only hatched shells remaining; however, he entered the tent and waited results. Before long "the hen greenshank came back, settled over the empty egg-shells, and began to rake them under her. Presently, in response to a soft call from the hen, the chicks came out of hiding in the grass and made their separate ways back to the nest, but the hen was preoccupied with the pieces of eggshell and paid more attention to them than to the chicks . . . she was restless and, after a little while, picked up a piece of shell with her bill and flew away, dropping it in flight . . . gradually all the shell was removed and the chicks came in for their full share of maternal devotion".

Seeing that greenshank chicks leave the nest within a short while of hatching, it is difficult to suggest what purpose, if any, there is in tidying up the nest. It is such observations as these that add value to the work of bird photography. FRANCES PITT.

# THE CHARM OF FLOWERS

## Flowers in Britain

Wild, Ornamental and Economic, and some Relatives in Other Lands. By L. J. F. Brimble. Pp. x+394+18 plates. (London: Macmillan and Co., Ltd., 1944.) 12*s*. 6*d*. net.

ONCE in a while a book appears which impresses the reader from the moment he first handles it. For a long time he has been conscious of a gap in contemporary literature that cries out to be filled; eventually a book appears, and the reader is immediately aware that this is the book for which he has been waiting. "Flowers in Britain" is unquestionably such a book. It was conceived with vision and has been nurtured with the assurance that such a book was badly needed.

Mr. Brimble has prepared it for "anyone who is interested in or wants to know something about flowering plants". These can be broadly divided into two groups. They are the non-botanists, who are interested in flowers for their appearance as much as anything else, and the botanists, who, while equally appreciative of the beauty of flowers, are more concerned with the formal aspects of their study. This book has something to offer to both groups, as well as to the intermediates who could not be classified as belonging to either one or the other.

British people have long had the reputation of being interested in their countryside. We have had striking proof of this during the War by the formation of natural history and field survey clubs in semi-static units of the Armed Forces, both at home and overseas. One such club in the Middle East has achieved considerable prominence, while, in Great Britain, the Royal Society has sponsored a promising movement in the Anti-Aircraft Command called the Nature Observation Scheme. The transfer of town-dwellers to rural areas, as well as the invasion of Great Britain by men from abroad who have made us more aware of the beauty of our own surroundings, has also served to deepen the regard for wild life. (Not many years ago, M. Herriot, the distinguished French statesman, was a guest in Oxford. He was asked by H. A. L. Fisher what had struck him most on this his first visit to England. "Two things," he replied, "first your rabbits and second your flowers.") Some of these people have particular interest in flowering plants, and to them this book would be a rich store of delight.

What has Mr. Brimble to offer here to the botanist? In the preface he writes: "One frequently finds that academic botanists, though thoroughly well-versed in the classification, structure, function, and so forth of the British native flora, are unfamiliar with garden flowers, many of which are really exotics. It is sometimes a matter of wonder to a non-botanist that many academic botanists, even those who have taken a university degree in the subject, know much less about the flowers of our gardens than the ordinary gardener". There is little need to labour his point, and many botanists will be grateful for the section on ornamental plants which appears under each family.

The order of the book can be briefly stated. There is a short introduction on the structure and classification of flowering plants, and then a series of chapters on the natural families, arranged, more or less, in evolutionary sequence. Each family is treated under the headings of plants indigenous to Great Britain, ornamental plants, and economic plants. The text is reinforced by more than thirty line drawings—all of them prepared by the author—and 160 photographs, and 18 coloured plates. The plates were painted by eminent floral artists; they are a tribute to their calling and to that of the printers who have prepared the plates for this work. Finally, the author has not forgotten the time-honoured part played by flowers in literature, and the book abounds with quotations as apt as they are entrancing.

In reading this well-merited praise, however, it must not be imagined that the book is without fault. Presumably, in trying to make the matter as clear as possible for the non-professional, Mr. Brimble has, on several occasions, fallen into the habit of 'writing down' to his reader. This has resulted in the production of some loose and grammatically unacceptable phrasing which might have been eliminated by severer proof-checking. There are a few factual errors, while, in some cases, the author has attributed to plants purpose and design. Further, some of the black-and-white photographs are not sufficiently clearly printed to illustrate the point under consideration.

Yet the standard of the book makes these criticisms seem almost churlish or carping. It is a magnificent production which should add considerably to the author's growing reputation as a writer of general biological works. When the next edition is printed, it is to be hoped that the supply position will have so much improved that the paper on which the text is printed becomes worthy of the matter.

T. H. HAWKINS.

# FOOD SCIENCE

## The Chemistry and Technology of Food and Food Products

Prepared by a Group of Specialists under the editorship of Dr. Morris B. Jacobs. Vol. 1. Pp. xvi+952. (New York: Interscience Publishers, Inc., 1944.) 10.50 dollars.

DR. MORRIS B. JACOBS, with the aid of forty-one expert collaborators, has set out to write a text-book in two volumes covering the whole field of food science and technology—a difficult if not an impossible task. Volume 1 is in two parts and contains 900 pages of subject-matter. Part 1 occupies 390 pages and is concerned with fundamentals—the physical chemistry of foods, the carbohydrates, lipoids, amino-acids and proteins, enzymes, vitamins and minerals, colouring matters, food spoilage and poisoning. All the sections are well written and largely up to date, and no doubt there are few research workers who would not profit by reading them. At the same time, many will feel that it is rather an unnecessarily heavy and rich hors-d'œuvre for the massive courses that follow.

Part 2, on foods, covers milk and dairy products, meats, fish, poultry and eggs, edible oils and fats, cereals, baking, fruits and vegetables, carbohydrates, confectionery and cocoa products, flavours, spices and condiments, coffee and tea. Each of these commodities is treated by an expert in the particular field, some of them of international renown. At the same time they are all very busy people, and one cannot help feeling that they would have written even better articles after the War when the demands on their time will be reduced.

In evaluating Volume 1 it is essential to remember

what Volume 2 will contain. We are told that it will be in four parts dealing with unit-operations and processes, sanitary and quality control, methods of preparation and methods of production. Dr. Jacobs, in his preface to Volume 1, points out that a certain amount of overlapping of the subject-matter is inevitable. Some of this could have been avoided; it is irritating, for example, to find canning and gas storage dealt with to the extent of about 200 words each, when presumably they will be considered in detail somewhere in Volume 2. For the same reason, it is difficult to criticize Volume 1 from, say, the points of view of omissions or meagreness in detail, not knowing what the next volume will contain.

The general level of the sections on foods in the volume under review is, as would be expected, excellent. The treatment of dairy products is obviously relatively meagre; but this is subject to the qualification in the preceding paragraph. The section on meat products deals sparingly with the changes in rigor mortis but compensates for this by a succinct and excellent statement on muscle pigments. Some readers will detect a touch of the quixotic in the statement that the 'drip' from frozen meat is dependent upon the duration of storage but is apparently unaffected by the temperature of storage. Others will be eager to know more about the asphalt treatment of hams and bacon. Dr. Mary Pennington discusses poultry and eggs with authority and experience, and will intrigue the reader with her reference to the fact that wax picking of poultry—the removal of feathers simply by dipping the birds in melted wax and stripping off the solidified wax—has now been supplemented by a "rubber finger picking machine" which removes most of the body feathers before the wax treatment. The sections on cereals and baking are outstanding. Prof. Geddes, however, does not mention the considerable difference in the riboflavin values found for cereal products in the United States and Great Britain; also his calculation that 12–15 per cent of germ is required to raise the vitamin $B_1$ level of patent flour to whole-wheat level applies only to the embryo fraction of the germ and ignores the two years old work in Britain which revealed the high content of vitamin $B_1$ in the scutellum fraction of the germ.

Two general criticisms can be levelled at the book. In the first place, it is disturbing that so many references are made to other published *books* and not to original papers. This fact not only tends to reduce the value of the book to the research worker but also raises doubt that a piece of original research is dealt with correctly and adequately. A further outstanding point is that the bulk of the references—perhaps more than 90 per cent—refer to American and Canadian work. It is hard to believe that the published work of the Food Investigation Board, the dairy research institutes, the food research associations and commercial laboratories in Great Britain merits less than 10 per cent of the references. There must be an explanation. Possibly it would help if we had one or two recognized journals for the publication of papers dealing directly with investigations in food technology—comparable with, say, *Food Research* or *Cereal Chemistry*. Whatever the solution, it is a challenging problem.

It is easy to criticize, and, having said that, let it also be acknowledged that this is probably the best book that has yet been written on food science and technology.

T. MORAN.

# THE ADVANCE OF BIOCHEMISTRY

## Annual Review of Biochemistry

James Murray Luck, Editor; James H. C. Smith, Associate Editor. Vol. 13. Pp. ix+795. (Stanford University P.O., Calif.: Annual Reviews, Inc., 1944.) 5 dollars.

IN his story of his visit to India, which has so arrested the attention of all of us, Prof. A. V. Hill has emphasized the need for biological research in particular in order to solve the many complex Indian problems.

The "Annual Review" may serve as an indication of the extent to which chemistry is allied with biology in the urge to extend knowledge. The findings are being far more rapidly applied to public welfare than of yore—in medicine, in food, in hygiene and in agriculture. If it be accepted that chemistry is the basic science, which has discovered how things are composed, what properties they have and how they will react, while physics provides an explanation of the rules of the chemical game, then the chemist must pioneer in the study of substances of physiological importance. He must know their structure, their properties and be able to explain the very complex reactions in which they take part. His difficulty has been, and is, to obtain them in sufficient quantity or of satisfactory purity for his purely chemical studies, so that real progress has had to wait on advances in laboratory technique as, for example, microchemical analysis, separation by selective adsorption.

The past decade has been fruitful in such methods, and progress has been the more rapid in consequence. It must be realized that a high standard of manipulative skill is required from the biochemist; further, that he is responsible for the soundness of his work, so that hasty publication is to be deplored.

In fact, the yearly output of biochemical papers is so great that no one can master even a tithe of them, nor indeed would his time be profitably employed. Hence the ever-increasing value of the "Annual Review of Biochemistry", now issued for the thirteenth time by Messrs. Luck and Smith, to whom all workers owe a very profound expression of thanks. For us in Britain it is the sixth winter of war and no such publication of eight hundred well-printed pages would be possible: our American cousins are more fortunate in escaping, or perhaps overcoming, the usual difficulties attendant upon the War, but our envy takes a very mild form, for we share on equal terms their gift to biochemists and are indeed grateful.

The 1944 volume takes its usual form, the subject being broken up into twenty-six sections, some of which are the joint responsibility of two authors. The standard throughout is high; the articles as a whole are more readable and less a catalogue of specialist progress.

The complex carbohydrates do not lose their attraction and are the subject of an admirable review by W. Z. Hassid. Those who listened to Prof. W. N. Haworth's very lucid Bakerian Lecture before the Royal Society know how apparently simple this complex subject can be made to appear; Dr. Hassid is almost as successful. One leaves the article wondering why Nature had to be so involved in creating such complexity from simple starting materials.

The proteins and amino-acids are no less important to-day, and their study, particularly that of the structure of the intact protein molecule, is returning

to fashion. Attention is perhaps focused on the preparation of proteins possessing unique and specific biological properties, that is, enzymes, hormones, viruses and immune bodies. Phosphorus compounds receive a special section commensurate with the increasing recognition of the part they play in reactions *in vivo*. Last year, sapogenins and saponins were reviewed under the heading of steroids; this year's story is limited to recent work on bile acids, sterols and steroid hormones. These are most complex substances; they play an important and universal part in living tissues.

Metabolism is broken up into many sections. The painstaking accumulation of facts and their verification is step by step contributing to progress—the significance of what are called trace elements in mineral metabolism is becoming more and more clear. Apparently the land animal of to-day has not entirely forgotten that it was once in bygone ages a marine organism.

The subjects of hormones and vitamins attract as much interest as ever, though the number of references quoted is not so large. Great interest is attached to the reports on nutrition and on nutritional deficiencies in farm animals. The War has both focused attention on such questions and given added stimulus to their study.

There is a well-written section on alkaloids by R. H. F. Manske : there seems to be no end to these compounds, and it is to be hoped that before long their inter-relationships and meaning will become clear. Even more interesting is the chapter by F. F. Blicke on synthetic drugs. The spectacular progress of chemotherapy has attracted the attention of the public at large, who are benefiting to-day from the drugs very soon after their discovery. Naturally fungi also require a section, written by E. L. Tatum. The discovery of penicillin has raised popular hopes that other moulds may contain a host of other specifics; but this article is severely scientific and more interested in a tentative interpretation of the biogenetic relationships of the mould products. All must ultimately have come from sugar and they represent end-products of carbohydrate metabolism; they belong to a rather limited number of chemical groups.

Only a very cursory survey of some of the reviews has been attempted, with the object of showing how much there is in the volume, which even at the risk of repeating what has been said in other years is once more certainly indispensable.

E. F. ARMSTRONG.

## PHYSICS AND PHILOSOPHY

### Physics of the 20th Century

By Pascual Jordan. Translated by Eleanor Oshry. Pp. xii+185. (New York: Philosophical Library, Inc., 1944.) 4 dollars.

THE story of the rise and development of twentieth century physics has been told so often and by so many 'leading world authorities', that, fascinating as it is, one's first reaction to any further author who proposes to guide the footsteps of the 'layman' along the now well-worn and familiar track is to ask (perhaps a little ungraciously): "Is your journey *really* necessary? Have you some points of view of interest to disclose which your predecessors have missed, or some matters of moment to discuss which others have, perhaps, insufficiently considered?" It may be said at once that, in the case of Dr. Jordan, the answer is definitely in the affirmative. While some authors have dealt more fully, and perhaps more clearly, with the experimental discoveries upon which the concepts of the new physics are based, and others have expatiated on the impact of these discoveries on industry, commerce and the social order, to Dr. Jordan the main interest of the story is in its intellectual content; to him it is primarily a spiritual adventure. "Our most wonderful moments of scientific evolution," he writes in his preface, "are experienced when it is shown that we must revise our ideas from the ground up to agree with a new concept. Modern physics effected many such changes; and in the most fundamental respects. That is what this book would like to tell about."

The 'layman' to whom Dr. Jordan addresses himself is thus not so much the scientist *manqué* as the philosopher, whether amateur or professional, who may wish to consider what bearing, if any, the new concepts of twentieth century physics may have on his own particular interests. It is true that philosophers have not so far shown quite as much interest in modern physics as some modern physicists have shown towards philosophy, and it may be readily admitted (as, in fact, the author does admit) that neither the methods nor the ultimate objectives of philosophy are those of physics. It is equally true, however, that even the most abstract philosopher can scarcely escape the intellectual atmosphere of the times in which he lives. There can be no doubt, for example, that the rise of dialectic materialism was largely aided and abetted by the existence of the 'mechanistic' school of physicists, who imagined (quite erroneously as it appears to us to-day) that, given the co-ordinates and momenta of all the atoms in the universe, it would be possible for a competent college of mathematicians to calculate all past and future history. The gradual abandonment by physics of the 'mechanistic' point of view, and the reasons which made this change of viewpoint inevitable, form the subject-matter of the present volume.

As far as may be, the author has endeavoured to present an unbiased and objective account both of the progress and the conclusions of modern physics, and has confined himself to indicating the particular points at which they appear to impact upon the conclusions of philosophy and theology. While it is, of course, well known that Dr. Jordan has his own ideas on the subject, he does not, in the present volume, intrude them upon the reader; or commit the tactical error of putting up the back of the philosopher by attempting to do his work for him.

It is unfortunate that the effect of the book in its English dress (it is a translation) should be marred by a rather involved style, and some infelicities and even obscurities in diction. How far this is due to the original manuscript, one cannot say; but only too often the translator appears to have been satisfied to transliterate the author rather than to try to present his ideas in current English; so that the unfortunate reader is left to wrestle simultaneously with unfamiliar ideas and a foreign idiom. The book, however, is one of real distinction; and readers interested in the fundamental problems and ideas of which it treats will be well advised to make the effort. Its appearance at the present time serves as a useful reminder that twentieth century physics is not solely, or even mainly, concerned with the gratification of the national animosities or material desires of mankind: it has a specific contribution to make to the ocean of universal learning.

# MOUNTAINS THAT HAVE TRAVELLED OVER VOLCANOES*

By DR. E. B. BAILEY, F.R.S.
Geological Survey of Great Britain

## Contrasts of Facies of Contemporaneous Formations in the Alps

GEOLOGICAL formations may vary greatly in character, or facies, from place to place. In the Swiss Alps the Mesozoic sediments show several facies associations, sufficiently definite to be given names. Of these the most commonly encountered is called Helvetian, while another of more restricted occurrence is called the Klippe facies. The name Klippe is taken from the German word for a cliff, because this particular facies is well displayed in some cliff-bounded mountains which form a conspicuous scenic element in the neighbourhood of Lake Lucerne. Equivalent formations exhibiting the Helvetian and Klippe facies are often so completely different in appearance that no one would guess their contemporaneity were it not for their contained fossils. This is truly amazing because the two facies in many localities lie cheek by jowl.

Bernhard Studer did more than anyone else to gather the facts. He found so early as 1834 that the Klippe facies was represented by the rocks of a considerable continuous mountainous area, later christened the Préalpes romandes, which reaches from near Geneva north-eastwards to Lake Thun; and also that it reappears in a surprisingly big proportion of boulders and pebbles contained in Early and Mid Kainozoic sediments along the northern face of the Alps. He deduced therefrom, quite correctly, that the Prealps represent the remains of a northern marginal chain which was being subjected to erosion in Early Kainozoic times. He further assumed, as a matter of course, that this chain had risen from below in the district where its remnants are still recognizable; and that its frequent non-appearance at the surface depends upon burial, partly beneath its own accumulated debris and partly under folds of Helvetian facies that have travelled a little distance from the south. Studer's conception failed to account for the abrupt change of facies, met, for example, on crossing the margin of the Prealps. It also contradicted every field observation of the structural relationships of Klippe and Helvetian complexes, for universally the Klippe complexes present the appearance of resting on top, not rising from below (Fig. 1). Still, it was the only interpretation that could be offered without invoking large-scale over-thrusting, and for this reason it remained all but unchallenged for fifty-nine long years.

In 1893 enlightenment came to Hans Schardt, who for the past fourteen years had been groping in the semi-darkness of the times trying to solve some of the riddles presented by the Prealps. Suddenly, he found himself standing in a flood of light which illuminated, not only the present position of the chain, but also the history of its development. There before him stretched the Prealps, a complex of Mesozoic and Kainozoic formations, entirely underlain by the local Kainozoic; an immigrant countryside fashioned of alien rocks that bespeak a southern origin; an erratic, as truly as any of the great blocks of Mont Blanc granite which we find jettisoned by vanished glaciers upon the flanks of the Juras—but an erratic, 75 miles long and 25 miles broad!

The Prealps are a composite erratic formed of a succession of superimposed thrust-masses. The higher thrust-masses have travelled farther from home than the lower, and each in turn has brought with it a distinctive stratigraphical facies. It was indeed the realization of the existence of multiple facies contrasts that cleared the way to understanding. Schardt had been brought up on Studer's two facies, Helvetian and Klippe, exposed side by side. The phenomenon was far too familiar to worry him as it really ought to have done. It therefore came as a mental shock and much-needed tonic to learn that Maurice Lugeon, through a find of fossils, had demonstrated another, and even more striking, facies contrast in the self-same area. Schardt realized at last that a far-travelled thrust-mass may often be recognized by the foreign characteristics of its rocks, just as a far-travelled man may often be recognized by the colour of his skin or the words of his speech. Bertrand, Suess and a few others had already looked

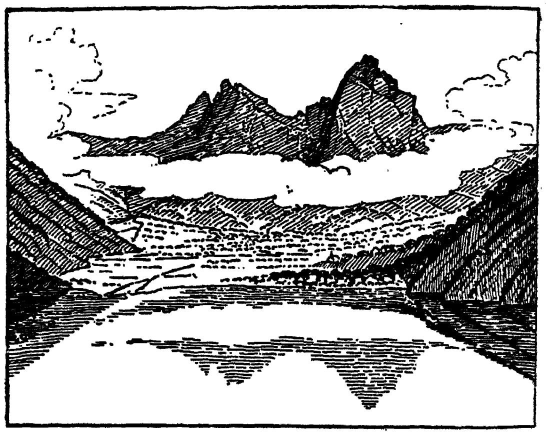

Fig. 1. THE MYTHEN FROM LAKE LUCERNE (AFTER ALBERT HEIM). This Klippe consists of Mesozoic rocks of Klippe facies. Heim has drawn a symbolic cloud to represent obscurities of pre-1893 interpretations. The grass below the cloud is on Kainozoic; from below on either hand emerge Mesozoic crags. All below the cloud is of Helvetian facies.

for help in this direction; but the regular employment of facies as a tool in the disentanglement of mountain structure was introduced by Schardt's appreciation of its value in relation to the Prealps.

The controversial spirit that was aroused by Schardt's "Origine des Prealpes romandes"[1] was reminiscent of that stirred by Darwin's "Origin of Species"; but opposition soon gave place to co-operation, and the new opportunities opened up for research led to a sustained, brilliant and most fruitful attack, altogether without parallel in the history of geology, upon Alpine problems.

Before leaving Schardt and his Prealps let us note that his re-interpretation of Studer's Klippe-facies marginal chain, as a superstructure riding upon adjacent Kainozoics, enabled him to account for its manifest gaps by invoking erosion, pure and simple. Studer, it will be remembered, had had to supplement erosion with burial. Moreover, the Klippe-facies pebbles enclosed in the over-ridden Kainozoics justified Schardt in claiming that the postulated erosion actually started long before the thrust mountains had ceased to travel over the floor of the sea which then lay to the north of them.

* Extract from a Friday discourse delivered at the Royal Institution on November 3.

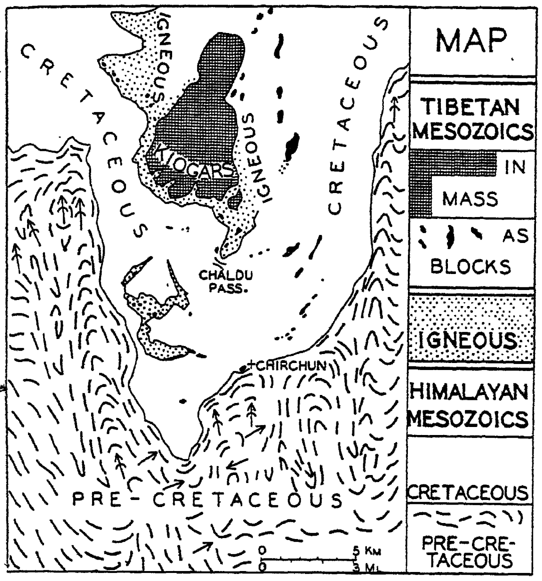

Fig. 2. BASED ON ARNOLD HEIM AND A. GANSSER.

## Facies Contrast in India

From Alps to Himalayas is a comparatively easy journey for a geologist. Both chains form part of one continuous Kainozoic range that stretches from Spain to the Dutch Indies; and both are in large measure fashioned of uplifted marine sediments that accumulated in an ancestral Mediterranean Sea called by Suess the Tethys. These sediments are particularly well displayed in the north-western Himalayas, where they form a mountainous belt 500 miles long, lying north-east of, and parallel to, the main line of giant snow-clad summits. The Spiti Shales of Mid Mesozoic age are their best-known component formation. For many centuries beautifully preserved fossil ammonites from these shales have been sold as sacred relics in the holy places of India. Thus we find that long before any geologist had seen these fossils *in situ*, examples had been described and figured as type specimens of new species and genera.

We are here concerned almost wholly with the south-eastern part of the belt, where it forms the divide between the Upper Sutlej and the head waters of the Ganges, at the same time serving as mutual frontier to Tibet and India. Here in the Kiogar-Chirchun district, C. L. Griesbach, C. Diener and C. S. Middlemiss in 1892 made a momentous discovery[2]. They found two markedly distinct facies of Mesozoic and Upper Palæozoic sediments in close juxtaposition (Figs. 2, 3). The first of these is now styled the Himalayan facies. It is characteristic of the 500-mile-long belt as a whole and differs notably from that of any time-equivalent known in Europe. The second, as yet only recognized in the Kiogar-Chirchun district and its continuation to the east, is spoken of as the Tibetan facies. On certain horizons it is almost identical with a locally developed facies found in the Austrian and Bavarian Alps at Hallstat, Hallein and (tell it not at peace conferences) Berchtesgaden[3,4].

Griesbach and Diener were Austrian in origin, as also was A. von Krafft, who later visited Kiogar and whose 1902 description furnishes the main foundation of our present knowledge of the district. Griesbach was for long a member of the Geological Survey of India, rising eventually to be its director. Diener was a professor at Vienna, who described many fossils collected by the Survey besides those he himself secured during the 1892 Expedition; von Krafft, like Griesbach, was on the staff of the Survey, but only for a short period. He died in 1901 before the appearance of his wonderful memoir to which reference has just been made.

In the Kiogar region the sediments of Tibetan facies are usually found as extensive masses or isolated blocks, partly overlying, partly involved in, a thick complex layer of igneous rocks; while the sediments of Himalayan facies usually underlie this igneous layer and are arranged among themselves, broadly speaking, in normal succession. Obviously, to reach their present extraordinary situation the Tibetan sediments must have travelled considerably. Still Griesbach and Diener, though well aware as time went on of current discussion of facies contrasts presented by Klippes in the Carpathians and the Alps, never admitted that the Tibetan masses of Kiogar had travelled horizontally through any significant distance. They thought it enough to imagine that the Tibetan assemblage had been pushed up in some unusual fashion to furnish a fault-breccia, and they regarded its facies peculiarities as a mystery totally unconnected with its anomalous structural position[5-8]. On the other hand von Krafft, Suess and later participants have clearly recognized that the facies contrasts between the overlying Tibetan and underlying Himalayan successions denotes great horizontal travel of one in relation to the other. Von Krafft attributed this travel to volcanic activity, operating either through the force of explosions or through the floating agency of lava streams (ref. 3, pp. 170, 173); but Suess[9] and his successors have attributed it to over-thrusting of the same type as is manifested

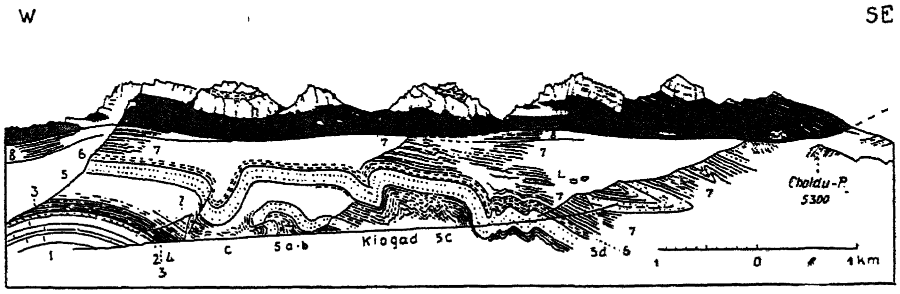

Fig. 3. KIOGARS (AFTER ARNOLD HEIM AND A. GANSSER).
Summits: Tibetan Mesozoic sediments, mainly Pre-Cretaceous.
Intervening: Igneous complex (shaded).
Lower slopes: Himalayan Mesozoic sediments: 1–4, Pre-Cretaceous; 5–8, Cretaceous, with radiolarian chert constituting 8.

in so many other mountain chains. Naturally the advocates of over-thrusting have sought to provide room in their theories for the emplacement of the igneous complex that separates the Tibetan and Himalayan sediments. In this direction there has developed considerable diversity of opinion.

## Igneous Rocks of Kiogar

Before discussing any of the rival Kiogar theories, it will be as well to enter into a little more detail regarding some of the rocks of the district. In doing so I shall avail myself in the main of von Krafft's observations, but shall accept certain important modifications recently introduced by Arnold Heim and August Gansser. The former, son of the distinguished geologist, Albert Heim, was brought up to geology from the cradle. His very name, Arnold, at once recalls his father's reverence for the great pioneer, Arnold Escher von der Linth. In 1935 Heim junior visited me in Glasgow, and I had the great pleasure of hearing of his preparations for an expedition to the Himalayas. In return I told him how I had been led to modify in an important detail Suess's interpretation of the Kiogar district, and I urged him to include this wonderful locality in his itinerary. Next summer, while I was assisting in the celebration of Harvard's tercentenary by propounding my story of mountains that have travelled over volcanoes[10], Heim and Gansser were hammering new facts out of these same mountains, to the great advantage of our science.

The topmost Tethys sediments of Himalayan facies in the Kiogar district belong to the Cretaceous System at the summit of the Mesozoic Group. The Lower Cretaceous is represented by some 2,000 ft. of greenish, glauconitic sandstone. Specimens from the Kiogar district, and also farther east, contain small fragments, which under the microscope are seen to correspond in type with lava-like constituents of the igneous complex lying at higher levels[11]. The Upper Cretaceous consists mainly of shales, for the first 2,000 ft., followed upwards by radiolarian cherts, amounting to another 1,000 ft. (von Krafft gives much smaller measurements).

I speak of these cherts as Upper Cretaceous, since such is the custom; but an early observation of Griesbach's near Dangpu, not far from the Sutlej, suggests that they may extend into the early Kainozoic[12]. Another interesting point to recall is that Griesbach, on first meeting with the associated igneous rocks, immediately and, as is generally agreed, correctly correlated them in a general way with other igneous occurrences already recorded by Strachey in 1851 at the Manasarowa Lakes and, much farther away, by F. Stoliczka in 1865 along the course of the Upper Indus. Though a general age correlation between the Upper Indus, Kiogar and Manasarowa rocks seems certain, I do not think there is a close structural connexion between the outcrops of the Upper Indus[13] on one hand and those of Kiogar and Manasarowa on the other. It looks rather as if research should be directed to establish a structural connexion between the Upper Indus belt and one that has recently been sampled by Gansser at Kailas (ref. 11, p. 187). The Upper Indus belt has been extended westwards to the Burzil Pass by D. N. Wadia[14]. *I confess that I have in previous publications employed Wadia's finds of fossils at Burzil on the misunderstanding that they came from the same structural position as is represented at Kiogar.* Fortunately there remains other evidence, which I could have put forward at the time, to demonstrate submarine volcanic activity at Kiogar, and this I develop below. The only known occurrence of igneous rock, which seems to occupy the Kiogar position in the Indus area, is a volcanic outlier in Zanskar, fifty miles west of Leh[15].

The radiolarian cherts constitute a new discovery due to Heim and Gansser. Of course 1,000 ft. of sediments cannot escape notice, but Griesbach in 1891 could only speak of what he saw as "a singular rock", while von Krafft later mistook it for "very thin-bedded tuff", that is, compacted volcanic ash.

In my 1936 approach to the Kiogar problem I had given a somewhat full account of Steinmann's great generalization regarding the oft-repeated world-wide association of radiolarian chert, serpentine and pillow lavas* (ref. 10, pp. 1718–1722). Accordingly, when Heim and Gansser announced their discovery at Kiogar they wrote: "Professor Bailey's ideas have proved to be of considerable bearing and he will be amazed that we have found indeed in great extension the radiolarites he probably has thought of, in conjunction with the igneous greenstones" (ref. 11, p. 146). To which I replied "Amazed ? Surely not ! Only sorry that Steinmann did not live to hear the welcome news"[16]. Though far from amazed, I was naturally delighted. Heim and Gansser's great find had completed the expected trinity. Serpentine had long been recognized and described in the igneous complex of the Kiogar region by von Krafft, who had submitted his material for microscopic examination to his colleague Thomas Holland (ref. 3, p. 136). It is also known in great bulk, associated with wide stretches of undecomposed peridotite, to the north of the Kiogar heights and near the Manasarowa Lakes (Heim and Gansser, ref. 11, pp. 183 and 179). Pillow lavas, too, had been described by von Krafft at Kiogar, though lack of experience prevented him from recognizing their true nature. In his account von Krafft quotes from Holland's descriptions such remarks as : "most of the rocks present the characters of lava flows, generally basic in composition, but much too altered for precise determination", and "many are distinctly amygdaloidal". He then turns to field aspects of the igneous complex and tells, for example, how he has met on the screes "round balls of amydaloidal andesite, approximately 2 ft. in diameter", which "on being broken up were found to contain calcite kernels, large in the centre, and decreasing in size towards the periphery". "In two places I observed," he added, "a spheroidal or sack-like structure in solid lavas, no doubt the result of weathering" (ref. 3, p. 137, also pp. 159, 165). It will be noticed that von Krafft attributed the ball or sack (that is, pillow) structure to the familiar phenomenon known as spheroidal weathering. This suggestion is negatived by two considerations :

(1) Rocks in the decomposed condition recorded in Holland's, and later, descriptions do not develop spheroidal weathering[17] ;

(2) Spheroidal weathering does not lead to development of central cavities such as are represented by the "calcite kernels" mentioned above.

On the other hand, von Krafft's description irresistibly recalls many familiar occurrences of pillow lava. The nearest analogue that I know is a pillow lava in Cornwall. In individual pillows, C. Reid and H. Dewey have said, "the amygdules are smallest in the outermost layers, and decrease in number but

* Steinmann did not admit that what we others call pillow lavas are really extrusive; but this mistake of detail is dealt with sufficiently in my 1936 paper.

increase in size towards the interior. The centre is often highly vesicular, with a large cavity from which the infilling calcite has been weathered out"[18].

Naturally when Heim and Gansser's descriptions appeared I looked to see if they had anything to say of the two exposures in which von Krafft had noticed spheroidal lavas. One not far from the summit, Kiogar 5, is figured and described as follows: "Red chert with radiolarians and associated, more or less siliceous limestones and marls" with "flags occur in such abundance" in the igneous mass "that they form a kind of stratification" (ref. 11, p. 156; the locality corresponds with von Krafft's in ref. 3, p. 159).

The inference I draw from the above facts seems to me secure: volcanic activity started in the Tethys somewhere near Kiogar early in Cretaceous times, and provided a little ashy material to the Lower Cretaceous sandstone; later, following an important development of radiolarian cherts, the local Tethys volcanoes became much more active and poured out submarine lavas, some of which assumed pillow structure; radiolarian chert continued to be deposited during quiet intervals; serpentines were intruded.

The same general assemblage of igneous rocks as presents volcanic relations to the underlying Himalayan sediments presents intrusive relations to the overlying Tibetan sediments. It is not only the coarse-grained serpentines that behave intrusively, but also the fine-grained lava-like rocks. In many cases these latter traverse the Tibetan sediments as narrow veins. In others they enclose entire blocks. The veining affects all members of the Tibetan succession, including certain occurrences which Heim and Gansser refer to the Cretaceous period (ref. 11, p. 162).

## Rival Theories

(1) We have already noted von Krafft's theory of volcanic transport of the Kiogar masses of Tibetan facies. He supports it by reciting many described examples of sedimentary material enclosed in volcanic ashes in other parts of the world; but he frankly admits that he has found no record of anything approaching the Kiogar scale (ref. 3, pp. 170, 173). Von Krafft's own descriptions and illustrations emphasize this difficulty of scale so clearly that as yet no one seems to have accepted his interpretation. Heim and Gansser, who have examined the ground, report that "the Kiogar limestone extends over many square kilometers, and permits to recognize its stratification over considerable distances", and also "the Kiogars are the remains of a thrust sheet coming from the Tibetan side, as already supposed in spite of v. Krafft's contradictory conclusions by E. Suess, F. Kossmat and E. B. Bailey" (ref. 11, pp. 160, 161).

(2) Suess, as just mentioned, interpreted in 1904 the Kiogar sediments of Tibetan facies as remnants of a far-travelled thrust-mass. He further interpreted the igneous complex that intervenes between the postulated thrust-mass and its Himalayan foundation as having been injected in this position during the forward progress of the thrust-mass.

(3) I was attracted to von Krafft's memoir by Suess, as presented in de Margeries' edition, "La face de la terre"[19], enriched with illustrations not to be found in the original of "Das Antlitz der Erde". I felt that Suess was in the main correct, but that he had overlooked an important aspect of the igneous complex, namely, that it includes representatives of submarine lavas as well as of subterranean intrusions. "I take it," I wrote in 1936, "that a Tibetan nappe has passed over a line of active submarine volcanoes; and that thereafter, for a while, magma has flowed along the thrust at the base of the nappe; but whether or not the original volcanoes were fed from a thrust plane has not been decided" (ref. 10, p. 1723). The above exactly expresses my present position after studying the host of new facts brought to light by the researches of Heim and Gansser. I consider that the Kiogar region furnishes the most remarkable geological monument in the world. It shows a Tibetan thrust-mass, which in its advance closed the mouths of Himalayan submarine volcanoes, and got itself riddled with multiple injections as a natural consequence. It combines the phenomenon of far-travelled facies, which Schardt illuminated in his 1893 interpretation of the Prealps, with that of tectonic smothering of vulcanicity, a conception sufficiently thought-provoking in itself.

(4) Heim and Gansser have advanced another variety of the volcano plus thrust theory. They consider that lavas and intrusions developed in late Cretaceous or early Kainozoic* times "in a remote Tibetan zone on the south side of the Trans-himalaya at the bottom of the deep sea and below it. Blocks slipped down from the coast and were embedded in the igneous flows. Then followed the thrusting towards the south" (ref. 11, p. 163). I do not think that the authors are likely to retain this "preliminary view", as they call it, because it is scarcely in accord with all the evidence they themselves have marshalled. They have been led to interpret the volcanic rocks, and many of the intrusions, as part of the far-travelled Tibetan thrust-mass, because they have found the igneous rocks in certain cases obviously affected by movement; and yet they are satisfied that the serpentines, though also obviously affected by movement, are quite certainly intruded into the Himalayan Cretaceous (ref. 11, pp. 184, 185). Similarly, in dissociating the volcanic rocks from the Himalayan suite and attaching them to the Tibetan suite, Heim and Gansser seem to forget that they have found debris of similar rock types in the Himalayan Lower Cretaceous sandstone. Moreover, they are driven to interpreting the radiolarian cherts between the lavas as Tibetan in contrast with the radiolarian cherts below the lavas, which latter they class as Himalayan. Regarding the cherts between the lavas they say: "The igneous flows must have been in relation to the deposition of the youngest sediments of the region which are regarded as Upper Cretaceous deep sea deposits. In the south-eastern Kiogars both are even mixed in a way as if the flow had penetrated and imbibed the flysch series [cherts in this case] chiefly along the bedding planes as it could hardly have been the case at the subaerial surface" (ref. 11, p. 162). I could name various other difficulties if space permitted.

## Exotic Blocks of the Kiogar-Chirchun District

In sketching the conditions prevailing in the Kiogar region, I have up to now avoided reference to the fact that many blocks of Tibetan sediment, together with associated igneous material, occur embedded in the Himalayan Cretaceous shales. The phenomenon of exotic blocks† enclosed in stay-at-home over-

* Elsewhere they (or probably only Gansser) claim these rocks as pre-Cretaceous (ref. 11, p. 184).

† The Tibetan blocks enclosed in the igneous complex are quite rightly called exotic blocks, but I have already discussed their relationships. Here I am only concerned with exotic blocks enclosed in sediments of Himalayan Cretaceous.

ridden sediments is one that is thoroughly familiar to students of the Alps. Again and again the question arises: Was this particular block introduced by sedimentary processes, such as land-slipping assisted by tunamis (earthquake-generated sea-waves), or by mechanical processes more directly connected with the operation of thrusting? In the present district there is, south-west of the Chaldu Pass (Fig. 2), a very prominent set of Tibetan sedimentary blocks, with Lias lettered L in Fig. 3. They are linked together by the customary igneous complex, including at one place pillow lavas, so as to constitute a unit three miles long, which has been carefully discussed by von Krafft under the heading "Area South of Kiogar Plateau" (ref. 3, p. 162). Though von Krafft was much averse to receiving aid from earth movement in his major problem, he clearly realized that the emplacement of this conspicuous assemblage of Tibetan and igneous rocks in the heart of the Himalayan Cretaceous sediments must be ascribed to folding and thrusting of some sort. Heim and Gansser confirmed this opinion and, calling the whole the "Chirchun thrust sheet", described it in architectural terms as a "tectonically lower exotic story", standing well below the main exotic story represented by the thrust-sheet that caps the Kiogar summits (ref. 11, p. 159). Several other exotic blocks included in the Cretaceous sediments of the district have been ascribed by the same three authors to mechanical introduction, and in all cases I agree.

In reading of these occurrences I have come to wonder whether the mechanism involved has not mostly depended upon outward flow of the unconsolidated Cretaceous clays when these have found themselves unevenly loaded by the advance of the Tibetan thrust-mass. Movement of clay under unequally distributed load is known to every civil engineer. Let me recall three representative examples.

(1) The Glengarnock iron foundry in Ayrshire piled up a great heap of slag on a clay surface. Presently the bottom of a neighbouring lake slowly rose and exposed the pile foundations of a forgotten crannog (lake village).

(2) Members of the Geological Survey have recently published detailed descriptions of adjustments by flow and rupture which have occurred again and again in response to changes of load dependent upon the protracted erosion of the valley systems of the counties of Northampton, Rutland and Lincoln. The main clay involved belongs to the Liassic formation of Mid Mesozoic age[20].

(3) At the foot of Beachy Head, the Chalk of the 500-ft. cliff is underlain by Upper Greensand and mobile Gault Clay, all three belonging to the Cretaceous System. Most of the chalk lies undisturbed; but its bottom portion, together with the greensand and gault, shows wonderfully complicated repeated small-scale thrusting, presumably due to outward upward flow of the yielding clay. The movement thus recorded very probably followed upon the marine erosion that has cut the present-day cliff (for the observational facts see Clement Reid, 1888, and Bull and Milner, 1925; for the interpretation see Hollingworth and others, ref. 20, p. 33).

My opinion is that most of the exotic blocks of the Kiogar-Chirchun district, in so far as they are included in the local Cretaceous sediments, are landslips in a very special sense, landslips that have slipped up and out from below the buried bottom of the advancing thrust-mass, rather than down and out from its uncovered front.

## Conclusion

A Tibetan thrust-mass invaded a Himalayan stretch of Tethys sea bottom, already occupied by submarine volcanoes. Driven underground, these volcanoes maintained a guerrilla attack by injection of molten material from below. Wear and tear due to withdrawal of overrun, overloaded mobile sediments added to the general confusion.

# SCIENTIFIC COLLABORATION BETWEEN INDIA AND BRITAIN

A COUPLE of months ago, a delegation consisting of six of India's leading scientific men arrived in Great Britain to study the organization of scientific research and of industrial research and development. The party consisted of Dr. Nazir Ahmad, director of the Cotton Technological Laboratory, Matunga, Bombay; Sir Shanti S. Bhatnagar, director of scientific and industrial research, India; Sir Jnan Chandra Ghosh, director of the Indian Institute of Science, Bangalore, and president of the National Institute of Sciences of India; Prof. S. K. Mitra, Calcutta, chairman of the Radio Committee of the Board of Scientific and Industrial Research; Prof. J. N. Mukherjee, professor of chemistry, University College of Science and Technology, Calcutta; and Prof. Meghnad Saha, of the University College of Science and Technology, Calcutta. The visit came to an end on December 1, when they left for a similar tour in Canada and the United States. On the previous day, at a farewell luncheon in London, Prof. Mitra summed up, on behalf of the mission, the impressions which they had received. He said:

"It is just over seven weeks since we arrived in Great Britain. Our visit to this country as guests of His Majesty's Government will presently be coming to a close. During our stay here we have received nothing but kindness, courtesy and, from all concerned, the desire to meet our slightest wishes. I take this opportunity of thanking most sincerely on behalf of my colleagues, His Majesty's Government, the Royal Society, the India Office and the Office of the High Commissioner for India for the trouble and care they have taken to make our visit as profitable as possible.

"On the eve of our departure, we are being asked by our friends about our impression of war-time England. To this we say that we have been greatly impressed by the wonderful spirit of team-work of the people, by the way in which the human power and the material resources of the country have been mobilized to fight the enemy and by the steadfastness of your will to win. In particular, in the matter of organizing scientific research, in which we were specially interested, we were struck by the manner in which scientific talent throughout the country has been mobilized and researches in the different branches of science co-ordinated to produce the most fruitful result in the quickest possible time. We were also delighted to see that the industries directly responsible for the huge war productions have realized the importance of scientific research. We felt that without this collaboration between science and industry on one hand and the Government on the other, the successful prosecution of the War would have been an impossibility. We are sure that this new spirit of collaboration for the common cause will continue after the War and find its way to our country for constructive work.

"We are also being asked if our mission in Great Britain has been a success. Has it been worth the time and trouble that His Majesty's Government has spent on this visit of ours ? To this we gratefully reply that we have seen and learnt whatever we wanted to see or learn. We have made contacts with the most distinguished men of science, industrialists and social workers of the country. Further, what to us has been of the utmost importance, we have had the fullest opportunity of studying the method of organizing scientific research for national needs to which I referred just now. We have visited many large-scale industries and have been taken round the most complicated manufacturing processes by the directors of the industries themselves. To us this has been a kind of a revelation. We now understand how much technical talent, large-scale organization and sense of team-work are necessary for efficient running of such industries. We hope to enlighten our countrymen on these matters when we return to India.

"One of our colleagues very aptly remarked that for the last seven weeks we were being put through an intensive course of adult education. So far as this aspect of the visit is concerned, we think it has been a success, because we hope we have not proved ourselves to be students who shirk work. Our object in coming to Britain, however, was not only to educate ourselves, but also at the same time to acquaint the people of Britain, by free and frank discussion and exchange of views, with our problems and needs. If by our visit we have, even in a small measure, been able to achieve this, we shall consider that our mission has been a complete success.

"The discoveries and inventions of science have annihilated space and time. We can now flash across space news which will go round the earth seven times in one second. We can cover distances in hours which formerly would have taken days. The world has in effect grown smaller. A result of this has been that the different nations of the world are being brought into closer and more intimate contact. In future, the different nations, big or small, will have to march together, whether they will or not. But this marching together will only be a source of strife and conflict if the different nations do not keep pace with each other. Nations which for some reason or other are left behind will be a drag on those moving forward and, by causing friction, will act as a brake on general progress. It is therefore the duty of the advanced nations, in their own interest, to see that none may be lagging behind, and to lend a helping hand to those who may unfortunately be so.

"I believe that it is the duty of every nation to strive for progress, as it is the endeavour of the plant to seek light. India has for a long time failed in this duty. It is no use discussing who has been responsible for this inaction. India is now striving for progress, and we are sure you will be ready to help us in our endeavour to seek light and freedom—freedom from want.

"In conclusion, I would thank, on behalf of my colleagues, all those who for the past seven weeks have been responsible for arranging our programmes, planning our visits and, in a hundred other ways, doing all that was necessary to make our visit as useful and as pleasant as possible. It is difficult to express adequately our gratitude to them for all they have done for us. The memory of this very pleasant visit, which has forged as it were a link of goodwill and fellowship between the scientific workers of your country and ours, will always be cherished by us. We shall be leaving the shores of Great Britain in the confident hope that India, just as she has been a partner of Great Britain in her struggles and tribulations in the dark days of war, will also be a partner of her prosperity in the days of peace in the near future."

# OBITUARY

## Sir Arthur Eddington, O.M., F.R.S.

THE death on November 22, at the age of sixty-one, of Sir Arthur Stanley Eddington is a great loss to science. In these days of specialization in science, it is given to few to have so wide a range of interests and to make contributions of outstanding merit in such diverse fields as he did. He combined to a unique degree an appreciation of the significance of new developments with great powers of mathematical analysis and keen physical intuition. A gifted expositor of the newest trends in physics, he was able to describe the most abstruse theories in clear and simple language; his name and writings were known throughout the world.

Eddington was born on December 28, 1882, at Kendal, Westmorland, of a Quaker family, his father being the headmaster of the Friends' School at Kendal. In 1902 he entered Trinity College, Cambridge, after having carried all before him at Owens College, Manchester. In the Mathematical Tripos of 1904 he was Senior Wrangler and in the following year was placed in the first division of the first class of Part II of the Tripos. In 1907 he was Smith's Prizeman and was elected to a fellowship at Trinity College.

In 1906 Eddington was selected by Sir William Christie, the Astronomer Royal, to fill the vacancy in the post of chief assistant at the Royal Observatory, Greenwich, caused by the appointment of F. W. Dyson as Astronomer Royal for Scotland. At Greenwich, he obtained experience in observational astronomy and a familiarity with its problems which were to stand him in good stead. Though his interests were primarily in theoretical investigations, he was able to appraise the value of observations and to test theoretical conclusions by means of the data

provided by observation. He discussed the observations made with the Airy reflex zenith tube and when, as the result of this discussion, it was decided to discontinue these observations and to employ the Cookson floating zenith telescope, loaned by the Cambridge Observatory, for the determination of the variation of latitude and of the constant of aberration, he planned the programme of observation with this instrument.

But Eddington's main interest at this time was in stellar motions. Kapteyn had but recently announced his discovery of the two star-streams. A rapid increase in knowledge of the proper-motions and radial velocities of the stars was taking place. Eddington used the new material, discussed it thoroughly, and confirmed and amplified Kapteyn's conclusions. In 1914 his "Stellar Motions and the Structure of the Universe" was published. This work contained an account of his own researches, but this was made subservient to the wider aim of giving an account of the many recent discoveries in sidereal astronomy and co-ordinating them to present, so far as was possible at the time, a coherent description of the stellar universe. In each of the main fields in which Eddington worked, he followed the same plan of publishing a connected account of the new advances, incorporating the work of others; students and investigators of these fields are greatly indebted to him for the valuable assistance which was thus provided for them.

In 1913 he was elected to the Plumian professorship of astronomy at Cambridge, which had become vacant through the death of Sir George Darwin; and the next year, after the death of Sir Robert Ball, he was appointed director of the Cambridge Observatory. In 1916 he took up the study of the radiative equilibrium of the stars. Schwarzschild had developed in 1906 the theory of the radiative equilibrium of a star's atmosphere, but did not apply the theory to the interior of a star. Eddington found that the extension of the formulæ to the interior of a star was not difficult. The theory was thought at first to be applicable only to the diffuse giant stars; it was considered that in the interiors of the dwarf stars, with their much greater mean densities, there would be an appreciable departure from perfect gas laws. The theory indicated that the bolometric magnitude of a gaseous star is independent of its stage of evolution and depends only on its mass. But in 1924, as the outcome of a careful discussion of all the reliable determinations of stellar masses, he found that the formulæ of the theory predicted correctly the absolute magnitudes of all ordinary stars, regardless of whether they were giants or dwarfs.

This discovery of the correlation between the masses and the luminosities of the stars was a result of outstanding importance. It showed that dense stars, such as the sun, obeyed the laws of a perfect gas; it also necessitated a complete revision of the then accepted views of stellar evolution. The two branches of the familiar Russell-Hertzsprung diagram must either represent loci of equilibrium points or, if there was evolution along them, it must be accompanied by appreciable loss of mass. The white-dwarf stars did not satisfy the mass-luminosity relationship; Eddington came to the revolutionary conclusion that the mean density of 53,000 of the companion of Sirius was not absurd and should be accepted; he pointed out that, if this density were correct, there should be an Einstein shift of its spectral lines of about 20 km. per sec., which was shortly afterwards confirmed by Adams at Mount Wilson. Eddington also investigated the problem of the Cepheid variable stars, on the hypothesis that their light variations were caused by periodic pulsations, and was able to account for the period-luminosity relationship obeyed by these stars, which had been found by Miss Leavitt at Harvard from the study of Cepheid variables in the Magellanic Clouds. In 1926 Eddington gave a connected account of these investigations in "The Internal Constitution of the Stars", while "Stars and Atoms" (1927) gave a fascinating and graphic description of the new results in a form intelligible to the general reader.

In 1926 Eddington gave the Bakerian Lecture of the Royal Society, taking as his subject "Diffuse Matter in Interstellar Space"; this was an important contribution to the understanding of the nature of the interstellar clouds. He found that ionization and capture form the main process of interchange between radiant energy and atomic kinetic energy in diffuse gas, and that this tended to raise the temperature to the level of the effective temperatures of stars, independently of the dilution of radiation. He modified the usual equilibrium formulæ for the amount of ionization to apply to matter in a field of evenly diluted radiation. The relative abundance of sodium to calcium was found to be very much greater than on the earth; the tremendous preponderance of hydrogen over all other elements was not realized at that time, and Struve later showed that the discordance was much reduced when it was assumed that hydrogen supplied the overwhelming majority of the free electrons. Eddington concluded that the stationary sodium and calcium lines in the spectra of early-type stars were produced by absorption by the interstellar cloud; but found that the dimming of distant stars by interstellar gas could not be accounted for unless it was assumed that these contained non-gaseous (meteoric) matter. This conclusion has since been amply confirmed.

Concurrently with these investigations, Eddington had also been occupied with the theory of generalized relativity. The War of 1914–18 had disrupted scientific intercourse, and Einstein's important papers were generally unknown in Great Britain. Eddington had received a copy from the Dutch astronomer, de Sitter, in 1917; he immediately accepted the new theory, perceiving its great importance. His "Report on the Relativity Theory of Gravitation", prepared for the Physical Society in 1918, provided the first account of the new theory in the English language and did valuable service in bringing the theory to the notice of British men of science. Many were converted to it; but many others, because of its revolutionary conceptions and the employment in its mathematical development of the tensor calculus, with which physicists and applied mathematicians were not generally familiar, were inclined to suspend judgment. The theory had accounted for the unexplained motion of the perihelion of Mercury, but further observational confirmation was needed to convince the sceptics. Sir Frank Dyson found that the total eclipse of the sun on May 29, 1919, would provide a particularly favourable opportunity for testing Einstein's prediction of the amount of the deflexion of rays of light by the sun. It was decided to proceed with the necessary preparations at Greenwich for two expeditions, to Brazil and the Island of Principe, though the state of the War at the time gave little hope that it would be possible for the

expeditions to set out. But the end of the War came in time, and Davidson and Crommelin from Greenwich went to Brazil, while Eddington and Cottingham went to Principe. Both expeditions made successful observations, and the results obtained supported Einstein's prediction of the amount of the deflexion, and did much to secure general acceptance of the theory. In "Space, Time and Gravitation" (1920) Eddington gave a non-mathematical account of the theory, to which he prefixed the very appropriate quotation from "Paradise Lost":

Perhaps to move
His laughter at their quaint opinions wide
Hereafter, when they come to model heaven
And calculate the stars: how they will wield
The mighty frame: how build, unbuild, contrive
To save appearance.

About this time there appeared a spate of popular accounts of the theory, but none could compare with Eddington's masterly presentation. In 1923 he followed this with "The Mathematical Theory of Relativity", which included an account of his own important contribution—a generalization of Weyl's theory of the electromagnetic and gravitational fields, based on the notion of parallel displacement. He emphasized that there must be woven into the structure of the world a standard of length making possible the comparison of lengths at different points in space-time.

Much of Eddington's later work was concerned with the development of the cosmological aspects of relativity theory and with the unification of quantum theory and relativity theory. Observations had shown that the external galaxies were receding from our own galaxy and from each other with speeds proportional to their mutual distances apart. This gave rise to the conception of the expansion of the universe. The small popular book "The Expanding Universe" (1933) gave an account of the phenomena to be expected in a finite expanding spherical universe, of the type first suggested by Einstein and later developed by the Abbé Lemaître. Eddington sought to find relations between the radius of curvature of space, the recession-velocity constant of the external galaxies, the number of particles (or the mean density of matter) in the universe and the physical constants, such as the ratio of the mass of the proton to that of the electron, the ratio of the gravitational to the electric force between a proton and an electron, the fine-structure constant and the velocity of light. The connexion between the constant of gravitation and Planck's constant was obtained by treating an Einstein universe first by relativity theory and then by wave-mechanics applied to the system of particles forming that universe. The mathematical account of the theory was given in "The Relativity Theory of Protons and Electrons" (1936) and was revised and completed in his lectures before the Dublin Institute for Advanced Studies, entitled "The Combination of Relativity Theory and Quantum Theory" (1943). These researches, to which Eddington gave much time and thought, have not yet carried general conviction, though the agreement between observed constants and the values found by pure reasoning are extraordinarily close. The extremely abstruse and complex nature of the investigations, which few can claim to have thoroughly understood, is no doubt responsible in some measure, but the purely deductive nature of the theory is an important contributory factor. Eddington wrote that:

"An intelligence, unacquainted with our universe, but acquainted with the system of thought by which the human mind interprets to itself the content of its sensory experience, should be able to attain all the knowledge of physics that we have attained by experiment. He would not deduce the particular events and objects of our experience, but he would deduce the generalizations we have based on them. For example, he would infer the existence and properties of radium, but not the dimensions of the Earth".

This is a philosophy of science that does not command general acceptance to-day. Nevertheless, it may well be that generations yet to come will regard Eddington's recent work as one of the most important and significant advances in science.

In "The Nature of the Physical World" (1928) being the Gifford Lectures for 1927, and "New Pathways in Science" (1935), being the Messenger Lectures at Cornell for 1934, Eddington dealt with the new developments in science—the theory of relativity, quantum theory, the principle of indeterminacy, the expansion of the universe, etc.—and with their effect on philosophical thought. Both books were essentially concerned with the question: What kind of knowledge does science give us? He showed that in dealing with the universe, science is confined to investigating its structure; it can tell us nothing of the nature of that which possesses that structure. It was not so much the particular form that scientific theories have now taken that is important, for they may in time give way to some fuller realization of the world, as the movement of thought behind them changes. Whatever changes may come, it will never be possible to go back to the old outlook. Eddington was a master of the English language, and these lucid expositions did more than any other books to make the intelligent layman aware of the new trends in science and of their philosophical implications.

Eddington was elected a fellow of the Royal Society in 1914 and was awarded its Royal Medal in 1928. He was president of the Royal Astronomical Society during 1921–23, and foreign secretary from 1933, and was awarded its Gold Medal in 1924. He was awarded the Bruce Gold Medal of the Astronomical Society of the Pacific in 1924. He was president of the Physical Society during 1930–32. He received honorary doctorates from twelve universities, and was honorary member, foreign member or foreign associate of many learned societies in Europe and America. He was created a Knight Bachelor in 1930 and received the Order of Merit in 1938. He was elected president of the International Astronomical Union at its last General Assembly in 1938. He was a great ambassador of science, who travelled and lectured widely.

Many in Great Britain mourn the passing of a friend and colleague while still in the zenith of his intellectual powers; their sense of loss will be shared by many others in all parts of the world, who have admired from afar his achievements and have received instruction and stimulus from his writings.

H. SPENCER JONES.

---

THROUGHOUT his career as an astronomer, Sir Arthur Eddington's connexion with the Royal Astronomical Society, both formal and scientific, was close and intimate. He was elected a fellow in 1906, was president during 1921–23 (a period of office which included the celebration of the centenary of the Society), received its Gold Medal in 1924, and

after H. H. Turner's death eventually inherited his office as foreign secretary, his corner-seat in the front row at meetings and, it is fair to add, his place in the affections of the fellows. He used its *Monthly Notices* as the medium of publication for almost all his fundamental contributions to science. Thus his early papers on star-streaming appeared there; his initial papers on Cepheid pulsations in 1916 appeared there; and these led in turn to his beautiful theory of the radiative equilibrium of the stars, in which the flow of radiation was first recognized as a basic process in the transfer of energy in stellar interiors, and in which the mechanical pressure of radiation was first shown to be an important element in the mechanical equilibrium.

The steps by which Eddington successively uncovered the dependence of relative radiation pressure on molecular weight, the dependence of that on ionization, the importance of radiation pressure in perhaps fixing the order of magnitude of the masses of the stars, and the probable gaseous character (on his hypotheses) of the whole interior of a star, are among the most fascinating in the history of mathematical physics. They led in turn to his recognition of the mass-luminosity law obeyed indifferently by giant and dwarf stars, which, however unsatisfactory still in its theoretical aspects, is an important supplement to our methods of ascertaining stellar masses. These steps accomplished, he returned to the question of the *chemical* constitution of stellar interiors, concluding (with others) that they are mostly hydrogen; and he completed in various ways his theory of pulsating stars. Further, he was a pioneer in the study of diffuse matter in interstellar space.

Eddington was ever a fighter for his ideas, allowing of no compromise when he had considered a matter and properly made up his mind. Many astronomers still remember titanic debates at the Royal Astronomical Society in which Eddington was protagonist and supreme defender of his own views; he asked no quarter, and he gave none. I think that a time may come when some of Eddington's more provocative conclusions on stellar structure may have to be re-valued, and that Eddington sometimes closed his eyes to the possibility of alternative attitudes to some of the scientific questions of the day. But as one who, in spite of wrestling with Eddington in public and in private in scientific disagreement, maintained always the happiest and friendliest personal relations, I join with heart-aching sincerity in the universal grief among the astronomical fraternity for one taken from us so unexpectedly, for a leader whose writings have been such an inspiration to lovers of astronomy and astrophysics, and for a dear friend to, and encourager of, all that was gentle, and wise, and witty, and satisfying in the sciences of which he was the devoted servant. Truly he was a great man.

E. A. MILNE.

---

ALL physicists deplore in the death of Sir Arthur Eddington the passing of a great leader in their science, whose genius they acknowledge as freely as they admit, in many cases, their inability to follow him in his most daring and difficult advances. These particular advances, however, form only part of his life's work: certain of his most striking achievements are based upon bold and penetrating applications of simple physical conceptions to problems not contemplated when they were elaborated. Nuclei stripped of all their electrons—of their crinoline, as Sir Alfred Ewing termed it—are a simple corollary of the nuclear theory of the atom: the pressure of radiation, measured in the laboratory, had been invoked to explain the behaviour of the tails of comets. Eddington seized upon these conceptions and, combining them with the laws of gravitation, evolved a theory within the comprehension of the ordinary physicist, which explained beautifully the general features of stellar structure and stellar evolution. Bare nuclei, together with the electrons freed from their normal orbits, readily represent a gas of great density, such as was required to explain the compactness of the dark companion of Sirius and other white dwarfs. By bold imaginative conceptions of this kind, combined with technical mathematical powers of the highest order, Eddington made of the stellar universe a physics laboratory where somewhat extreme conditions prevailed, but nevertheless a physics laboratory.

His early work on relativity and his observations that established the bending of light in a gravitational field were likewise matters which appealed to every physicist. His later work on the connexion of the theories of relativity and quantum mechanics, which enabled him to relate the velocity-distance relation of the spiral nebulæ to the number of elementary particles in the universe, and his mysterious number 137, are hard matters for many of us, but we feel that it is impertinence to criticize that which we do not understand, when it comes from a master. Here are great attempts at the solution of great problems, made in a manner that commands respect and admiration.

Eddington was a man of extremely wide interests in physics. In 1920 he wrote for the Physical Society a report on the Relativity Theory of Gravitation, which met an urgent need, and he was president of the Physical Society during 1930–32. He took a very active interest in the doings of the Society, and his presidential address on "The Expanding Universe" will be long remembered. When in the chair he showed a surprising familiarity with almost every aspect of physics that came before the meeting.

Eddington's more popular works, such as "Stars and Atoms", had a wide appeal to all interested in physical science. Physicists rejoiced to see the esoteric delights of their subject exposed with such perception, daring and vivacity. The width of Eddington's reading was shown nowhere so clearly as in his quotations, always apposite, which were drawn from an astonishing variety of authors. To the book just cited is prefixed a most apt citation from the Swiss anatomist and physiologist Albrecht von Haller, whose poetical works cannot be familiar to most English men of science,

> "Ich häufe ungeheure Zahlen,
> Gebürge Millionen auf,
> Ich setze Zeit auf Zeit und Welt auf Welt zu
> Hauf",

and elsewhere Descartes, Lucretius, Omar Khayyam, H. G. Wells, Isaac Newton, Cardinal Newman, Lewis Carroll, Milton, Shakespeare and the Bible among others are called upon.

It can be seldom, if ever, that one who was a master of the most abstruse technicalities of scientific thought could have been able to express himself as lucidly, as charmingly and as individually as Eddington does in his more popular works. He had in him something of the prophet, but one with a very much more amiable and conciliatory style in his writings than that of most prophets. E. N. DA C. ANDRADE.

# NEWS and VIEWS

## Sir D'Arcy W. Thompson, C.B., F.R.S.: A Professorial Record

"YOU will never live to my age, without you keep yourselves in breath with exercise, and in heart with joyfulness"—and so successfully has Sir D'Arcy Thompson fulfilled the injunction of Sir Philip Sidney that ere Christmas Day he will have completed sixty years as professor of natural history. On December 22, 1884, at the age of twenty-four, he was elected, as its first incumbent, to the chair of natural history in the newly opened University College of Dundee. Here, as at Edinburgh Academy, he was fortunate in his environment of good companions: his unsuccessful competitors for the chair included J. T. Cunningham, W. E. Hoyle and Patrick Geddes; his new colleagues in due course numbered among them as young professors who later gained wide recognition, Sir Patrick Geddes, who had accepted the chair of botany, Sir Alfred Ewing, principal and vice-chancellor of the University of Edinburgh, Sir William McCormick, secretary to the Carnegie Trust for the Universities of Scotland, Sir James Walker, professor of chemistry in the University of Edinburgh, and Sir William Peterson, principal of McGill University, Montreal. In 1897, University College, Dundee, which had begun as an independent institution, became an integral part of the University of St. Andrews, and in 1917, on the retiral of Prof. W. C. McIntosh from the chair of natural history in St. Andrews, which he had occupied since 1882, it was a fitting and natural move that D'Arcy Thompson should be transferred to the senior chair. His predecessor retired in his seventy-ninth year; in his eighty-fourth Sir D'Arcy continues to teach with vigour and to take part in many activities outside the University.

In his early years in Dundee, Sir D'Arcy Thompson, like many another, was drawn to the marine invertebrates, particularly to the Cœlenterates and Bryozoa, and began the building up of a collection which eventually contained an unusual number of authenticated representatives of invertebrate species. But his interests were wide, and his appointment as a delegate to the Behring Sea Fisheries Conference in 1897 and his selection in the following year to be scientific member of the Fishery Board for Scotland gave public recognition to what has remained a main aspect of his scientific work. For forty years, that is until the Fishery Board was disbanded recently, he retained its scientific membership and guided the development of its scientific investigations; and his own published papers on the statistics of fisheries and the distributional occurrence of rare species of fishes show his personal predilection. This was but one of many interests—the classics and the natural history of the ancients, the perfection of adaptation in many creatures, the influence of physical law in moulding the parts of animals, growth and form; but perhaps the fundamental and rejuvenating interest throughout has been the outlook of the born naturalist, which finds its satisfaction by the shores of the North Sea or in the woods of the Spey valley.

## Conway Evans Prize: Sir Thomas Lewis, C.B.E., F.R.S.

THE presidents of the Royal Society and of the Royal College of Physicians have awarded the Conway Evans Prize to Sir Thomas Lewis, in recognition of his great contribution to medical knowledge on the normal and abnormal mechanisms of the heart and circulation of the blood. This prize, in accordance with the will of the late Dr. Conway Evans, who was medical officer for the Strand District, is awarded from time to time for scientific work of outstanding distinction. It was first given to Sir Charles Sherrington in 1927 and since then to the late Dr. John S. Haldane in 1933, and to Sir Frederick Gowland Hopkins in 1938. It will be seen that so far the prizes have been awarded infrequently with the intention that they should be given only in recognition of outstanding contributions to science, thus fulfilling the intention of the donor. Sir Thomas Lewis has worked essentially in a field which he has called 'clinical science', and he has clearly indicated how the modern developments of science in general can be applied to the many problems of medicine at the bedside.

## An International Office for Education

DR. HARLOW SHAPLEY, speaking on behalf of the U.S. Office of War Information, recently broadcast an address in the United States with reference to an International Office for Education. He pointed out that both education and lack of education play a part in our present world-wide troubles. The high technical training in the armed forces, and also in the war factories that back the armies and navies, represents a type of education that is indispensable in our effort to bring back peace and social sanity to the world. But it is a lack of education—a deficiency in elementary social education, or a perversion of it, that has brought the madness of totalitarian war upon us. In too many parts of the world the fundamental education has not been planned so as to teach us how to live and let others live intelligently in the kind of world that modern technical civilization has given us. In the social evolution that is necessary for a good and progressive world society, we must have a basic education so widespread, and so democratic in spirit, that demagogues cannot easily lead us into inhuman and selfish and false creeds. We must have, if possible, in all grades of our educational systems, the desire and freedom to question statements, to challenge dogmas. We must question our teachers, and not be blindly led by them. We should encourage internationalism in our leaders. We must have, especially in our elementary schools, a universal recognition that there are international allegiances as well as national responsibilities, that we are a part of a world-wide human society.

It is to facilitate the reform or the improvement of educational systems in all countries that the setting up at the earliest time practicable of an International Office for Education is suggested. Such an office is not intended to be a temporary affair, concerned with rehabilitation problems. Such reconstruction work is necessary and immediately urgent. Steps toward carrying it through are well under way. But of necessity, rehabilitation is a re-establishment of the conditions that existed before the blight of war passed over the land. Rehabilitation is in a sense backward-looking, rather than forward-look and evolutionary. The advocated International

Office for Education should be set up for all time, and be oriented toward the future, toward a socially improving future. Particular educational systems in any country are not suggested. Rather, the International Office should act as a clearing-house for educational ideas, an information centre for the educators and for the educational bureaux and ministries that need guidance and specific assistance in the improving of their work. In the specialized sciences and arts there have long been useful international unions. In their limited fields such organizations have shown how relatively simple it is for the people of all nations to co-operate. What has been done in the sciences can certainly be done in the general educational field. The great usefulness of the International Labour Office during the past two decades shows how important, for international understanding, an organization of this sort can be. That the establishment of an International Office of Education appeals to Americans of all sorts has been indicated by the rapid support received from scores of important organizations—from church, labour, industry and education—and from numerous members of the National Congress. It is hoped that the American Government will join with the other free governments of the world, in an official recognition of the essential part of education in the planning for a better and more peaceful world.

## Visual Aids in the Schoolroom

THE remarkably comprehensive and suggestive paper recently read at the Royal Society of Arts by Mr. R. W. Moore, headmaster of Harrow, calls for special comment. The progressive teacher, he said, is alive to the uses of the epidiascope, and films have established themselves as an important subsidiary in schools. In the past, visual factors have been neglected, no doubt. Yet, he said, we must ask ourselves whether worse dangers than those of neglect are not involved in the uncritical multiplication of visual aids now prevalent in some quarters. Illustration is confused with explanation. Excess of detail, leading to distraction and irrelevance, abounds. True, the development of new processes promises a great enrichment for teacher and pupil; but our chief need is that of a psychology of education which will take account of these visual adjuncts and order them. The subjects which most need visual aids, said Mr. Moore, are science, history and geography. Of the three, he proceeded, science is the best case, because observation has long since been recognized as basic in the scientific tradition, and also scientific men have a professional bias towards, and a mechanical dexterity in, the manipulation of visual aids. History is the most difficult to accommodate to such aids. Geography stands between. It is the study of man in his natural environment. As a subject, it has only recently emancipated itself from the verbalism of the academic tradition. It should have its roots in observation and begin with local investigation. But how are we to extend the process towards a knowledge of world geography? How is the child in a poor London school to observe India and South America? Films are here intensely valuable, but the material available is sadly thin. The present needs are: (1) that research and experiment be made inside the teaching profession towards ascertaining what visual aids are appropriate to particular subjects and purposes, and (2) that there should be thorough co-operation between teachers and manufacturers before and during production.

## A Natural Elastic Polyester

SOME of the newest and most fascinating developments in applied science lie in the field of high polymers—and yet the story of high polymers, since they form the principal physico-chemical basis of life, is one of the oldest and most fundamental in the world. Most natural chain-molecules still cannot be synthesized by man; but he can build many others that are not found in Nature. Among the latter were thought to be the polyesters, first synthesized by Carothers and Arvin in 1929. It is reported now by A. R. Kemp and H. Peters (*India Rubber World*, **110**, 639; 1944) that what seems to be very likely a polyester constitutes the highly elastic skin that fits tightly round the seeds of *Smilax rotundifolia* Linn. The ripe berries usually contain three seeds about ½ cm. in diameter, each enclosed in a membrane about 0·003 cm. thick. On removal, the membrane is found to be stretchable by 300–400 per cent and to give then a typical X-ray fibre photograph with a probable fibre period of about 22½ A. This finding, taken in conjunction with chemical analyses carried out on the skins both before and after hydrolysis with alcoholic caustic potash, indicates that the main component is a polyester formed by the repeated condensation of a unit having 17 or 18 carbon atoms in the chain with two hydroxyl side groups, the suggested empirical formula of the monomer being $C_{18}H_{36}O_5$. The conclusions are for the present tentative, but they are by no means unconvincing, and the results of further investigation—very much worth while—will be awaited with interest.

## Earthquake in Japan

ONE of the most violent earthquakes of recent years was recorded by the seismographs at Kew, West Bromwich, New York and Bombay, and probably throughout the world, on December 7. At West Bromwich it was recorded at 4h. 48m. 38s. G.M.T., and the waves were so violent that the recording mechanism was upset. At Fordham, New York, the Rev. J. J. Lynch believes from a preliminary investigation of his records that two shocks were recorded, at 12.49 and 12.53 a.m. (local time). The Japanese News Agency stated that the Island of Honshu was affected, and that it was believed that the epicentre was in the Sea of Nshu. The Tokaido district was affected and also Shizuoka, Hamamatsu, Nagano and Nagoya, the third largest city of Japan. There was some damage to property and a seismic sea-wave affected Shizuoka. It appears unlikely that further details will be obtainable from Japan until the end of the War; but this was undoubtedly a very great earthquake, and when the records are examined closely the epicentre will be found more precisely.

## The Phosphorus Cycle in Nature

FOR his presidential address to the Geological Section of the Congress of the South Eastern Union of Scientific Societies, held on October 14, Dr. K. P. Oakley took as his subject "Man and the Migrations of Phosphorus". For some time after the earth's formation, the phosphorus cycle in the sea was simple, the phosphate ions being built up into the earliest forms of organic life and released again at their death, the only loss occurring through the precipitation of phosphate ions accumulated at the lower levels, with the formation of sedimentary rock phosphate beds. Following the emergence of life from the sea and the

colonization of dry land, a soil-plant-animal-soil cycle arose, from which phosphorus was removed in small quantities in the formation of bone beds, fossil fish or guano deposits. With the development of agriculture in historic times, however, the phosphorus cycle has been seriously upset, for systematic cropping reduces the reserves in the soil more quickly than they can be renewed from fresh sources. In the past few centuries man has attempted to restore the phosphorus balance by the use of fertilizers, derived largely from natural deposits; but he has also accelerated the transference of phosphorus from plant and animal life to the sea, thus speeding up its cyclical migration in a two-fold manner. Although this has been of undoubted benefit to man, it will ultimately lead to a state of bankruptcy with regard to the element. The world reserves of workable mineral phosphate are within measurable distance of exhaustion, and although new sources may be discovered, a planned economy in their utilization seems called for, as no substitute for phosphate exists and it is essential to the survival of a large human population. The address, which includes a historical account of phosphatic fertilizers, is to be published in the January issue of the *South Eastern Naturalist and Antiquary*.

## Mathematics in China

IN addition to work directly for the war effort and in spite of difficulties of communication, mathematicians in China are able to produce a considerable amount of new work of the highest quality. In particular, we may mention Prof. L. K. Hua, of the Tsing Hua University in Kunming, whose visit to Cambridge during 1936–38 will be remembered. The following information has been received through the British Council Cultural Scientific Office at Chungking. Prof. Hua has just completed a booklet on additive prime number theory which will be published by the Academy of Sciences of the U.S.S.R. The first of a series of papers on the theory of automorphic functions of a matrix variable has just been published in the *American Journal of Mathematics*. Related to this is a theory of modular functions connected with linear associative algebras, which is so far unpublished. Another field in which Prof. Hua has been working is that of the geometry of matrices, related to topological algebra. In addition, Prof. Hua has continued his studies in the geometry of numbers and, in extending theories due to Minkowski and Dr. K. Mahler, has discovered a new type of convex body.

## Astronomical Observations in Spain

IN the issue for 1944 of the *Boletín Astronómico Del Observatorio De Madrid*, E. Gullón supplies a résumé of the observations of solar prominences during September–December 1939. Owing to the removal of certain equipment from Valencia to Madrid and to other causes, observations could not commence before September 1. Sunspot observations during the same period were made by E. Gullón and Martín Lorón with the 20-cm. Grubb equatorial, and the results are shown on pages 14–16. Solar prominences during 1940 were observed by E. Gullón and the results are given in the same form as those observed during 1939. The last section of the bulletin deals with sunspot observations carried out by E. Gullón and Martín Lorón at Madrid and Valencia in 1940. Those at Madrid were made by means of a Herschel helioscope mounted on the 20-cm. Grubb equatorial, focal length 3 m., and those at Valencia were made with another equipment of a similar type on the 15-cm. Grubb, and with a focal length 2.20 m.

## Swedish-made Drugs

ACCORDING to the August issue of the *Anglo-Swedish Review*, a new local anæsthetic has been discovered which in several respects far surpasses novocaine, which Sweden had hitherto to import. This new anæsthetic has been named *LL* 30, the letters standing for the names of two young scientific workers Lövgren and Lundquist, and the figure representing the number of anæsthetic compounds tried and discarded during their six years of investigation. *LL* 30 is now being made on a commercial scale by the Astra concern of Södertälje not far from Stockholm, where penicillin is also being manufactured. Sulphonamide preparations are being manufactured from Swedish raw materials, and its price is now down to half that of the imported foreign preparations.

## Books on Historical Medicine and Science

THE annotated catalogue issued by Schuman's, 30 East 70th Street, New York, under the name of "Medical Miscellany List 'J' ", includes, besides a large number of miscellaneous works on medicine and science, two sections devoted respectively to neurology and psychiatry and war medicine. The miscellaneous works include books by Baillou on epidemiology, diseases of the skin by Alibert, anthropology by Blumenbach, physiological optics by Helmholtz, as well as the first fifteen volumes of the *Memoirs of the Royal Academy of Surgery of Paris*. Among the books on neurology and psychiatry are works by Brown-Séquard, Freud, Janet, Kraft-Ebing, Puschmann, Spallazani and Vesalius. The section on war medicine contains Hans von Gerssdorff's field book of surgery (1528), John Pringle's "Observations on the Diseases of the Army" (1765) van Swieten's "Diseases incident to Armies" (1776) and works on the American Civil War (1861–1870), including documents concerning the United States Sanitary Commission.

## Announcements

AFTER nearly two years in China, Dr. Joseph Needham, director of the British Council Cultural Scientific Office in China, has returned to Great Britain for consultations. He will be returning to China early in the New Year.

PROF. J. M. MACKINTOSH, professor of public health in the University of London, has been appointed dean of the London School of Hygiene and Tropical Medicine as from January 1, 1945.

AT the annual general meeting of the Scientific Instrument Manufacturers Association of Great Britain, Ltd., the following officers were elected: *President*, Mr. F. Wakeham; *Vice-Presidents*, Mr. J. Hasselkus and Mr. J. T. Offer; *Hon. Treasurer*, Mr. J. E. C. Bailey; *Hon. Secretary*, Mr. G. A. Whipple.

THE Association of Scientific Workers is organizing a conference to discuss the use of science in the post-war world, to be held at the Caxton Hall, London, S.W.1, during February 17–18, 1945. Further particulars will be obtainable in due course from the Association of Scientific Workers, Hanover House, 73 High Holborn, London, W.C.1.

## Unification of the Theories of Photon and Meson

ONE of the puzzling features of the modern theory of matter is the considerable number of different ultimate particles: photons, neutrinos, negative and positive electrons, mesons, protons and neutrons. To each type of particle corresponds a certain type of field, and all these fields are supposed to exist simultaneously in space.

Attempts at unification were successful only in the frame of classical electrodynamics; it is possible to consider the electron as a singularity of the electromagnetic field. But this idea could not be adapted to quantum theory.

To-day, particles of any type are considered as quanta of the corresponding field (in the same way that photons are the quanta of the electromagnetic field), and their interaction can be described by a coupling of the fields. This interaction produces not only the phenomena of collision and combination of different particles, but also the self-energy of single particles, and is therefore the clue to the understanding of the different masses. But this theory is extremely complicated and has so far yielded no positive results.

It would, therefore, be of advantage to have a simple example where the interaction of two types of fields can be studied rigorously with the help of simple mathematics. I have found that the interaction of two fields with even spin provides such an example.

A field with spin 0 is described by a scalar wave function $\chi$. The simplest Lagrangian density as used in the elementary theory of the scalar meson is

$$\mathfrak{L}_0 = \tfrac{1}{2}(\nabla\chi)^2 + \tfrac{1}{2}\eta_0^2\chi^2, \quad . \quad . \quad . \quad . \quad (1)$$

where $\nabla$ means the 4-dimensional gradient $\partial/\partial x_\alpha$ ($\alpha = 1, 2, 3$; $x_1, x_2, x_3$ space co-ordinates, $x_4/ic$ time). The constant $\eta_0$ is connected to the rest mass $m_0$ by

$$\eta_0 = \frac{m_0 c}{\hbar} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (2)$$

A field with spin 1 is described by a 4-vector wave function (components $\varphi_1, \varphi_2, \varphi_3, \varphi_4$); the most general Lagrangian density is

$$\mathfrak{L}_1 = \tfrac{1}{2}(\nabla\wedge\varphi)^2 - \tfrac{1}{2}\lambda(\nabla\cdot\varphi)^2 + \tfrac{1}{2}\eta_1^2\varphi^2, \quad . \quad . \quad (3)$$

where $\wedge$ indicates the vector product (with 6 components $\partial\varphi_\beta/\partial x_\alpha - \partial\varphi_\alpha/\partial x_\beta$) and . the scalar product. $\eta_1$ is again proportional to the rest mass.

If $\eta_1 = 0$ and $\lambda = 0$, one has the ordinary Maxwellian theory of the vacuum. The addition of the $\lambda$-term is of no great consequence as the solutions are usually restricted by the condition that the quantity

$$\Phi = \nabla\cdot\varphi \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (4)$$

vanishes (Lorentz condition). If the term with $\eta_1$ is added, one has the vectorial meson theory.

Now I suggest that the interaction of these two fields should be considered, *assuming in both of them that the mass term is zero.*

$$\eta_0 = 0, \ \eta_1 = 0. \quad . \quad . \quad . \quad . \quad . \quad (5)$$

The simplest possible interaction is

$$\mathfrak{L}_{01} = \mu\chi(\nabla\cdot\varphi), \quad . \quad . \quad . \quad . \quad . \quad (6)$$

where $\mu$ is a constant of dimension reciprocal length. It is easy to see that no other independent interaction exists which is relativistically invariant and quadratic in the wave functions.

The total Lagrangian

$$\mathfrak{L} = \mathfrak{L}_0 + \mathfrak{L}_1 + \mathfrak{L}_{12} = \tfrac{1}{2}(\nabla\chi)^2 + \tfrac{1}{2}(\nabla\wedge\varphi)^2 - \frac{\lambda}{2}(\nabla\cdot\varphi)^2 + \mu\chi(\nabla\cdot\varphi) \quad . \quad . \quad (7)$$

then leads to the field equations

$$\nabla^2\varphi - \nabla\Phi = s, \quad . \quad . \quad . \quad . \quad . \quad (8)$$

$$\nabla^2\chi = \mu\Phi, \quad . \quad . \quad . \quad . \quad (9)$$

where

$$s = \nabla(\lambda\Phi - \mu\chi) \quad . \quad . \quad . \quad . \quad . \quad . \quad (10)$$

can be considered as a charge-current vector. From (8) one obtains the continuity equation for $s$:

$$\nabla\cdot s = 0, \quad . \quad . \quad . \quad . \quad . \quad (11)$$

which, however, is not an identity, but implies in virtue of (9) and (10)

$$\nabla^2\Phi = \frac{\mu}{\lambda}\nabla^2\chi = \frac{\mu^2}{\lambda}\Phi \quad . \quad . \quad . \quad (12)$$

Now one can establish wave equations for $\chi$ and each component of $\varphi$ separately, by applying the operators $\nabla^2$ and $\nabla^2 - \mu^2/\lambda$ to (8) and (9):

$$\nabla^2\left(\nabla^2 - \frac{\mu^2}{\lambda}\right)\chi = 0, \quad . \quad . \quad . \quad . \quad (13)$$

$$\nabla^2\left(\nabla^2 - \frac{\mu^2}{\lambda}\right)\nabla^2\varphi = 0. \quad . \quad . \quad . \quad (14)$$

These equations have solutions of the form of plane waves, representing particles with energy $E$ and momentum $\mathbf{p}$; for these solutions the operator $\nabla^2$ corresponds to multiplication with $(E/c)^2 - \mathbf{p}^2$. Hence there are two types of waves possible: one moving with the velocity of light corresponding to particles with rest mass zero, photons; the other with smaller velocity corresponding to particles with finite rest mass

$$m_0 = \frac{\hbar\mu}{c\sqrt{\lambda}}, \quad . \quad . \quad . \quad . \quad . \quad . \quad (15)$$

which behave, therefore, like mesons. A simple discussion shows that in the case of the photon $\chi = \Phi = 0$, three of the four components of $\varphi$ are arbitrary (the fourth being determined by the Lorentz condition $\nabla\cdot\varphi = 0$); whereas in the case of the meson $\chi$ and $\Phi$ are not zero and $\varphi$ has only a longitudinal component equal to $\chi$.

The result is that particles of spin 0 and 1 without rest mass are transformed by the simplest interaction into two new types of particles, one still having the rest mass zero (photon), the other a finite rest mass (meson).

Photon and meson seem to be different phenomena of the same quantized field. The theory as indicated here is over-simplified; for example, the wave functions are treated as real quantities, whereas there is evidence for the meson field being complex (for otherwise mesons could not carry electric charges). Moreover, the provisional character of these considerations is obvious as they exemplify how meaningless it is to neglect any kind of particle. All particles together form a single field of great complexity. One can venture the suggestion that, by adding to the scalar and vector fields treated here, a Dirac field

without mass term, the result will be a transformation into new types of particles with finite rest mass and spin $\frac{1}{2}$. This theory, however, will be much more complicated, since the interaction terms of the vector field $\varphi$ and the spinor field $\psi$ are of the third order (type $\varphi(\psi\psi)$ ). One has to apply perturbation theory, and it is well known that this has so far always led to infinite values of the self-energy. But recent investigations carried out by Dr. H. W. Peng, in my Department, have shown that this is due only to insufficient mathematics. Therefore it can be expected that Peng's method of secular perturbations will allow the mass problem to be tackled as sketched here.

## Excretion of Penicillin in Man

PENICILLIN is rapidly eliminated from the human body, and 40–99 per cent of an injected dose can be recovered from the urine within four hours in normal cases. There is some evidence that the drug is actively secreted by the renal tubules[1,2]. In cases of severe azotæmic nephritis, penicillin has been demonstrated in the blood for so long as ten hours after a single injection, although in a normal person after a dose of 25–50,000 units it would have disappeared in three hours.

There were recently admitted to this Hospital two patients, both of whom had had incomplete abortions at the sixteenth week of pregnancy and both of whom developed extreme oliguria directly afterwards. In each case this condition lasted for ten days before recovery began, and during this period such urine as was passed consisted of a glomerular filtrate with evidence of little tubular function. This is shown by Table 1, from which it may be seen that even at high blood urea levels there was only a low urea concentration in the urine (cf. extrarenal azotæmia, in which urinary urea may reach 4 per cent), that chlorides were not retained even though the plasma values were far below normal (560–620 mgm. sodium chloride per 100 c.c.), and that creatinine was concentrated to a small extent compared with the 'normal' ratio of about 100[3].

TABLE 1. CONCENTRATIONS ARE GIVEN IN MGM. PER 100 ML., AND THE DAYS REFER TO THE NUMBER OF DAYS OF OBSERVATION.

| | Case I | | Case II | |
|---|---|---|---|---|
| | 2nd day | 10th day | 2nd day | 10th day |
| Urine vol. (ml.) | 15 | 180 | 165 | 150 |
| Urea in blood | 174 | 530 | 255 | 320 |
| Urea in urine | 170 | 600 | 800 | 600 |
| Chlorides (as NaCl) in plasma | 590 | 360 | 400 | 320 |
| Chlorides (as NaCl) in urine | 160 | 255 | 215 | 305 |
| 'Apparent' creatinine in plasma | 8 | 18 | 8 | 12 |
| 'Apparent' creatinine in urine | 6 | 9 | 67 | 50 |

These temporarily self-nephrectomized persons provided an opportunity of observing the fate of injected penicillin, for physiological as well as therapeutic reasons. 45,000 units of a preparation issued by the Therapeutic Research Corporation were injected intra-muscularly, and bacteriostatic assays were made upon serum samples at intervals afterwards. Bacteriostasis was measured in slide-cells, using the Oxford standard strain of *Staphylococcus aureus* as test organism. The results are given in Table 2.

TABLE 2.

+ = bacteriostasis.
± = partial bacteriostasis compared with control.

| | Hours after injection | Serum dilution | | | | | |
|---|---|---|---|---|---|---|---|
| | | 1/1 | 1/2 | 1/4 | 1/8 | 1/16 | 1/32 |
| Case I. | 3 | + | − | + | + | ± | + |
| | 7 | + | + | + | − | + | + |
| | 18 | + | + | + | + | − | − |
| | 26 | + | + | + | + | − | − |
| | 32 | + | + | ± | − | − | − |
| | 45 | + | + | − | − | − | − |
| | 72 | + | ± | − | − | − | − |
| | 107 | + | − | − | − | − | − |
| | 131 | − | − | − | − | − | − |
| Case II. | 1 | + | + | + | − | − | + |
| | 6 | + | + | + | − | − | + |
| | 20 | + | + | + | + | ± | − |
| | 26 | + | + | + | + | ± | − |
| | 48 | + | + | + | + | − | − |
| | 68 | + | ± | − | − | − | − |
| | 92 | + | − | ± | − | − | − |
| | 116 | + | − | − | − | − | − |
| | 116 (with penicillinase) | − | − | − | − | − | − |

In both cases urine samples collected during the test periods were assayed for penicillin by the ring test[4], but none contained detectable amounts.

The second patient was given a further injection of 47,500 units five days after the first. The 24-hour urine volumes on the succeeding days were 150, 480, 600 and 1,260 c.c. Her serum, taken three days after this injection, still caused complete inhibition of growth of staphylococci at a dilution of 1:1, and partial inhibition at 1:2 (effect abolished by penicillinase). On this occasion the urine excreted during the twenty-four hours following injection caused inhibition of growth in the ring test corresponding to $\frac{1}{2}$–1 unit of penicillin per c.c., but subsequent specimens caused negligible inhibition.

The failure to recover penicillin from the urines ($p$H 6·8–7·6, and preserved with toluene) of case II must have been due both to grossly impaired glomerular and tubular function. As judged by creatinine values, however, concentration of the urine by tubular reabsorption of water was still occurring to the extent of at least five times, although chloride reabsorption and urea excretion were greatly deficient. If penicillin were concentrated in the urine solely by reabsorption of water, it seems probable that it would have been sufficiently concentrated in the urine to have been detected in the ring test. However, such evidence for active tubular secretion is suggestive only.

The main conclusion to be drawn from these two cases is that in the absence of significant renal excretion of penicillin this drug is slowly inactivated in the body, but will nevertheless remain detectable for five days.

## Ammonia Excretion and the Clearance of Mepacrine

It has been found that the urinary excretion of mepacrine has a relation to the excretion of ammonia. The simplest description of this empirical relation is that the mepacrine clearance from the plasma is directly proportional to the rate of excretion of ammonia. This may be expressed thus:

$$\frac{UM \times V}{PM} = k\, UNH_3 \times V, \quad . \quad . \quad . \quad (1)$$

where $UM$ is urinary mepacrine in micrograms/litre; $V$ is volume of urine in ml./min.; $PM$ is plasma mepacrine in micrograms/litre; $UNH_3$ is urinary ammonia in mgm. $NH_3$-N/100 ml.; and $k$ a constant equal to 2·4.

Equation (1) may be written in the form:

$$PM = \frac{1}{k}\,\frac{UM}{UNH_3} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (2)$$

In this form the relation can be used to estimate plasma mepacrine concentration from the urinary concentration of mepacrine and ammonia only, without regard to their rates of excretion. The relation has been studied and found to hold between the following limits: $UM$ from 260 to 4,900 micrograms/litre; $V$ from 1 to 10 ml./min.; $PM$ from 12·2 to 40·2 micrograms/litre; $UNH_3$ from 3·4 to 59·5 mgm. $NH_3$-N/100 ml.

The accompanying table shows the plasma mepacrine concentrations ($PM$ calc.), calculated from equation (2) for two separate urine samples obtained from each of ten subjects, compared with the plasma mepacrine concentrations directly determined by Masen's method[1] on blood samples drawn in the middle of each urine-collecting period ($PM$ obs.).

OBSERVED PLASMA MEPACRINE CONCENTRATION ($PM$ OBS.) COMPARED WITH THE CALCULATED VALUE ($PM$ CALC.).

| Volunteer No. | Period | $PM$ (obs.) microgram/litre | $PM$ (calc.) microgram/litre |
|---|---|---|---|
| 1 | I | 40·2 | 38·2 |
| | II | 32·8 | 41·8 |
| 2 | I | 32·3 | 33·8 |
| | II | 29·3 | 33·4 |
| 3 | I | 28·5 | 25·8 |
| | II | 26·6 | 22·7 |
| 4 | I | 25·4 | 26·2 |
| | II | 25·0 | 24·6 |
| 5 | I | 23·8 | 16·2 |
| | II | 23·0 | 24·6 |
| 6 | I | 19·9 | 30·6 |
| | II | 18·4 | 14·5 |
| 7 | I | 18·2 | 19·4 |
| | II | 17·4 | 16·1 |
| 8 | I | 16·3 | 14·6 |
| | II | 15·8 | 17·4 |
| 9 | I | 14·3 | 13·7 |
| | II | 13·9 | 14·6 |
| 10 | I | 13·0 | 14·6 |
| | II | 12·2 | 14·0 |

The standard deviation of the differences between $PM$ (obs.) and $PM$ (calc.) was found to be $\pm$ 4·0 micrograms per litre, with a mean plasma concentration of 22·2 micrograms per litre, whereas the standard deviation of $PM$ (obs.) (mean of triplicates) was itself $\pm$ 3·5 micrograms per litre.

The striking relation expressed in equation (1) has, so far as we know, not previously been reported. There is no reason to suppose that this relation is confined to the excretion of mepacrine. It possibly depends on the fact that mepacrine may behave like a substituted ammonia compound, in which case the relation may be applicable to the excretion of other such compounds.

For example, the observations by Haag *et al.*[2] that quinine is excreted more rapidly in acid urine than in alkaline suggests that this drug behaves like mepacrine. This possibility is being investigated.

## Viscero-Motor Reflexes

STIMULATION of the sensory nerves of the abdominal viscera has given mixed results in the hands of different observers. Miller and his colleagues[1,2] obtained movements of the hind legs and belly muscles on centripetal stimulation of the mesenteric nerves of decapitated cats. Squeezing the intestine and traction on the mesentery were also effective. Lewis and Kellgren[3], on the other hand, obtained no movement of the legs or belly muscles on pinching the duodenum, but did record a rise of blood pressure. Pinching the pancreas caused both muscle movements and rise of blood pressure. McDowall[4], in 1942, stated that occlusion of the carotid and vertebral arteries of a decerebrated cat produces a 'spinal' preparation devoid of shock, and that certain stimuli, such as stretching the gut, cause marked limb movements. He pointed out that a successful result is obtained only if the preparation is not over-ventilated.

We also find that the presence or absence of spinal reflex movements following stimulation of the intestine depends on the preparation of the animal. When the brain of the cat is destroyed above the second cervical vertebra, no, or only very small, movements of the hind limbs follow a strong pinch of the duodenum, but a pinch of a small part of the head of the pancreas causes strong movements; a rise of blood pressure follows each pinch. This confirms the findings of Lewis and Kellgren. On the other hand, when the spinal cord is transected in the upper thoracic region and the cat then decerebrated, a gentle squeeze of any part of the small and large intestine causes strong movements of the hind legs. Other effective stimuli include scraping or scratching the serous coat or heating the gut, and also pulling or rubbing the mesentery. We find that the small intestine is less sensitive along its free border than near the attachment of the mesentery. Responses follow mechanical or thermal stimulation of an adequate area of the gut or repeated stimulation of a smaller area. All stimuli have been applied to the outside of the intestine, and it is not yet possible to define the site of origin of the afferent impulses.

When the response to visceral stimulation is tested some three hours after the operation under ether anæsthesia, superficial and deep reflexes of the hind legs are very lively and easily elicited in both preparations. It is curious that there is so little correspondence between the general reflex activity of the hind limbs and the responses to visceral stimulation. The viscero-motor responses may deteriorate to extinction without apparent change in the general reflex activity of the limbs. It must be recalled that

the animal with the head pithed is maintained alive by artificial respiration, and it is possible that the failure to elicit viscero-motor responses is related to the abnormal ventilation.

## Role of Acetylcholine and Vitamin $B_1$ in Nervous Excitation

A YEAR ago a short report of our work under the same title was given in *Nature*[1]. Since then new data have become available, which will be summarized briefly.

Stimulation of the branch of the vagosympaticus supplying the heart of the frog leads to the liberation of a second substance, besides acetylcholine, which diffuses into the fluid in the canula on which the heart is fixed. We have identified this substance as aneurin (thiamin) or an aneurin-compound[2]. Heart-fluids collected during resting periods do not contain the substance. Stimulation of the sympathetic component alone (nn. accelerantes) has no effect on the liberation of the substance. The result of stimulation of the mixed nerve varies from individual to individual. Pure vagus stimulation can be produced from the medulla oblongata. Stimulation with a special electrode produced in the heart more of the substance than is found otherwise. Oxidation with potassium ferricyanide in alkali transforms the substance into thiochrome, soluble in butanol, with the characteristic fluorescence of thiochrome. Ultra-violet of short wave-length (less than 290 mμ) destroys aneurin in solutions[3], *in vivo* in the nerve[4], and the same was found with the substance in heart-fluids collected during stimulation periods.

The amount of aneurin or aneurin-compound set free on vagus-stimulation was determined by two independent methods: (*a*) with our very sensitive fluorometer, making use of monochromatic illumination and a vacuum photocell, connected with a specially balanced amplifier[5]. After a total of five minutes stimulation (with intervals) of the vagus, $1 \times 10^{-8}$ gm. aneurin was liberated in each cm.$^3$ of heart fluid. (*b*) Growing *Phycomyces blakesleeanus* on heart fluids obtained during stimulation periods produced good growth. Fluids from resting periods of equal duration gave no or only negligible growth. Calibrating the growth-curves with aneurin solutions gave about the same amount of aneurin liberated during stimulation as with the thiochrome method. We cannot say at the moment if it is free aneurin or a compound of aneurin; aneurindiphosphate (cocarboxylase) is excluded.

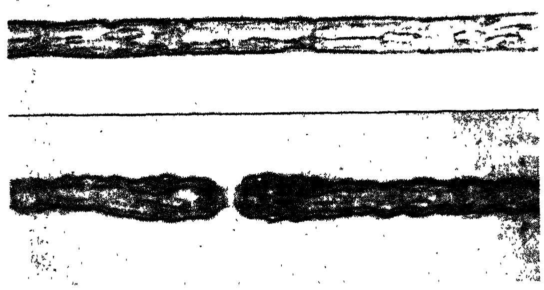
Adrenalin shows fluorescence on addition of alkali, an optical effect which might introduce an error; but it is insoluble in butanol in those concentrations which might interfere, and the fluorescence of the substance in our experiments is only produced by the addition of potassium ferricyanide. Interaction of adrenalin is ruled out by these chemical facts and by the biological observation that stimulation of the sympathetic chain does not produce a liberation of a substance with the same optical properties as the substance found on vagus stimulation.

Polarographic records were taken from heart fluids collected from resting periods, sympathetic stimulation and vagus stimulation. The 'vagus fluids' showed a regular and very considerable increase of the characteristic step in the polarogram near 1,950 mV. This effect corresponds exactly to the effect which was discovered two years ago[6] taking the polarogram of extracts from nerves, frozen in the excited state in liquid air, and to the effect obtained upon stimulation from the cut end of cholinergic nerves dipping into Ringer solution. 'Vagus fluids' from a stimulated heart, extracts of stimulated cholinergic nerves and solutions used for bathing stimulated nerves all show the same polarographic effect. The increase cannot be due to the liberation of free aneurin, the lowest concentration of chemical pure aneurin detectable by polarographic analysis being $1 \times 10^{-5}$. The aneurin liberated on stimulation in the cholinergic nerve and at the end of the vagus in the heart is an active compound with a strong catalytic effect on the dropping mercury electrode at 1,950 mV. At the same time, this compound has the same effect as vitamin $B_1$ on *Phycomyces blakesleeanus* and yields thiochrome on oxidation. The artificial aneurin compounds so far studied did not satisfy these three requirements at the same time. The aneurin compound set free in the heart on vagus stimulation must be considered as a special form of aneurin.

Löwi called the substance (acetylcholine) liberated on vagus stimulation in the heart "Vagusstoff", so long as he was not sure of its exact chemical nature. We propose to call the second substance which is liberated together with acetylcholine and which has the properties of an aneurin compound, "2. *Vagusstoff*".

The normal polarographic technique requires several minutes in order to take one record. This was not satisfactory in the study of the time relation between stimulation and appearance of the active aneurin compound in the bathing fluid into which the cut end of a stimulated nerve was dipping. We designed, therefore, a new apparatus in which the polarogram appears on the screen of a cathode ray oscillograph. With this apparatus the whole effect is visible as soon as the substances reach the dropping mercury electrode. Varying the distance between the cut end of the nerve and the dropping mercury electrode and taking the nerve out of the fluid at the end of the stimulation showed that the active substance is produced at the moment, or a few milliseconds later, when the excitation wave reaches the cut end of the nerve. Even if the liberation of this aneurin compound is connected with recovery from excitation in nerve, as we think to-day, the time relations between excitation, liberation of the substance and recovery are very short.

Ultra-violet photomicrographs of living single nerve fibres (nerve-muscle preparation) have been taken with $\lambda = 280$, 275 and 257 mμ. The accompanying photomicrographs reveal the existence *in vivo* of the protoplasmic marginal net, described by Cajal and Nageotte on fixed preparations, and the extensive development of this net on the node. Taking the ultra-violet absorption spectrum of *living* nerve fibres with an apparatus designed very much along the lines developed by Caspersson[7], a distinct maximum of absorption was found at $\lambda = 265$ mμ. It corresponds to the maximum of absorption of aneurin. This maximum disappeared after treating the fibres with potassium ferricyanide. The disappearance on chemical treatment confirms this view, because this



ABOVE, LIVING SINGLE NERVE FIBRE OF FROG. CADMIUM SPARK, $\lambda = 275$ m$\mu$, QUARTZ CONDENSER AND CORRECTED QUARTZ OBJECTIVE AND OCULAR. SIZE OF FIBRE DIAMETER, 8 $\mu$.

BELOW, NODE OF RANVIER, DIED DURING EXPOSURE (1 MIN.), SAME TECHNIQUE AS UPPER PHOTOMICROGRAPH.

substance is transformed into thiochrome in nerve as was shown previously[8], and then the maximum shifts to 375 m$\mu$. The measurements are complicated by the photochemical action of the short-wave ultra-violet on the single nerve fibre[4]. This action is immediate at the nodes of Ranvier; the internodal section is protected by the nerve sheath. The photochemical decomposition of the sheath can be followed by serial photographs. In one series, by chance one photograph was taken just before the last excitation wave passed the single fibre and the next photograph was taken one second after impairment of conduction. Impairment of conduction was due to disconnexion of the axis cylinder produced by ultra-violet radiation (275 m$\mu$), clearly visible on the photomicrograph.

The acetylcholine and aneurin content was measured in mammalian nerve fibres during Wallerian degeneration. Acetylcholine disappears very rapidly after section of the nerve, as previously found by other authors[9]. In our experiments the ability of nerve to synthesize acetylcholine was maintained so long as the nerve remained excitable. Aneurin has quite a different curve. The loss is great in the first twenty-four hours and slows up from then on, so that a certain level is maintained even after seventy-two hours of degeneration. Protracted degeneration was observed after the administration of aneurin, using as a test the degeneration of the nerve fibres in the cornea of the rabbit, visible with a special slit-lamp and vital staining method.

The experiments reported confirm the conception that acetylcholine formation is essential for the excitation or recovery process and that aneurin is a reservoir substance closely connected with the formation and disappearance of acetylcholine[10].

Full details will be presented elsewhere. I am indebted to the Rockefeller Foundation for grants in aid of this work.

## Metabolism of Symmetrical Trinitrotoluene

THE recent publication by Channon *et al.*[1] of a paper on the T.N.T. metabolism in the rabbit induces us to record similar investigations carried out during the past two years with rats, human volunteers and munition workers.

For the estimation of diazotizable amines a spectrophotometric method, based on the principles of the method of Bratton and Marshall[2] for sulphonamides, was used. A simplified colorimetric method was made available to the Commonwealth Department of Health in June 1943.

The excretion of diazotizable amines was found to be roughly proportional to the intake of T.N.T. In the rat the recovery (15–20 per cent of ingested T.N.T.) was lower than found by Channon *et al.* with the rabbit, while on the average 40 per cent of small doses (10–30 mgm.) given to human volunteers was excreted in this form.

The reduction products in the urine were separated as follows: after acid hydrolysis (one hour in 1/8 $N$ hydrochloric acid) the acid urine was extracted with ether in a continuous extraction apparatus giving Extract I. The residual urine was then neutralized with sodium carbonate and the more strongly basic compounds extracted with ether in the same manner (Extract II). Both ether extracts were washed with sodium bicarbonate, afterwards with sodium hydroxide. The sodium hydroxide extracts contained much more diazotizable amino-compounds than the bicarbonate extracts, the substances extracted evidently being amino-nitrocresols. The weakly basic dinitrotoluidines were extracted from the first ether extract with 20 per cent and concentrated hydrochloric acid, the strongly basic nitrotoluylene diamines from the second extract with 1 per cent hydrochloric acid. 4-amino-2.6-dinitrotoluene and 2.4-diamino-6-nitrotoluene added to normal rats' urine could be recovered quantitatively by this procedure, the former in the first, the latter in the second extract.

The ether-extractable pigments of munition workers' urine consisted of 60–75 per cent dinitrotoluidines, 10–25 per cent nitrotoluylene diamines and 10–15 per cent of amino-nitrocresols. In the rat the results were, however, different: nitrotoluylene diamines predominated (50–60 per cent), while dinitrotoluidines and amino-nitrocresols formed the remainder in about equal proportion.

From the human dinitroluidine fraction we isolated 4-amino-2.6-dinitrotoluene (m.p. 175°, no m.p. depression with pure compound m.p. 175°) and a product with melting points varying between 128° and 136°, more lightly coloured than the 4-amino-compound, less basic and extracted from ether fully only by concentrated hydrochloric acid. Acetylation with pyridine-acetic anhydride revealed that the latter was still a mixture; the acetyl compound consisted of flat square-ended yellow needles and some fine colourless needles. The greater part melted at 159°, but a small part remained solid up to 196°. Since the acetyl compound of 6-amino-2.4-dinitrotoluene forms yellow needles, melting at 159–160° (Channon *et al.*[1]), while that of the 4-amino-compound crystallizes in almost colourless needles of m.p. 227°, the product was evidently the 6-amino-compound with some 4-amino-compound admixed. The Webster test, which we carry out in alcohol-ether mixture 1 : 1, adding small amounts of alcoholic potash, gave with ether extracts of human urines the brownish-purple colour

indicated the presence of 4-hydroxylamino-2.6-dinitrotoluene. The products present in the human urines are thus mainly the same found by Channon *et al.* in the rabbit.

In the dinitrotoluidine fraction from the rat we found only 4-amino-2.6-dinitrotoluene. The nitrotoluylene diamine fraction gave a compound very similar in properties to 2.4-diamino-6-nitrotoluene. It was less soluble than the latter in chloroform and crystallized in orange needles of m.p. 145° which gave a large melting-point depression with pure 2.4-diamino-6-nitrotoluene of m.p. 138°. The acetyl compound crystallized in deep yellow triangles or twinned prisms, m.p. 336°. The assumption that this compound is the isomeride (2.6-diamino-4-nitrotoluene) was ruled out by the observation that it can be obtained in good yield by feeding 2.4-diamino-6-nitrotoluene to rats. Analyses have shown that the substance is 5-nitro-*m*-phenylene diamine, for which Flürscheim[3] reported m.p. 141°. The rat is thus able to remove the methyl group from T.N.T. The mother liquors contained 2.4-diamino-6-nitrotoluene.

## Specific Protective Influence of Alanine in Differential Tissue Destruction by Hexenolactone (Parasorbic Acid)

MEDAWAR'S differential 'mesoderm inhibitor', originally obtained from malt, ungerminated grain and oranges, has been closely reproduced through synthesis by Medawar, Robinson and Robinson[1], who are not entirely certain whether their malt-distillate factor is optically active δ-hexenolactone or an allied substance. Because of structural similarity with panto-lactone, which combines with β-alanine to form pantothenic acid, synthetic *dl*-δ-$\Delta^{\alpha\beta}$ hexenolactone and its natural equivalent (probably parasorbic acid) were suspected of entering somehow into pantothenic acid metabolism, possibly by competition with panto-lactone.

Kuhn and Jerchel[2], independently of Medawar *et al.* and following a different procedure, also prepared an optically inactive unsaturated δ-hexenolactone and established its structural identity with parasorbic acid. Kuhn, Jerchel, Moewus, Moller and Lettre[3] confirmed the differential inhibition of fibroblasts at concentrations of this lactone which did not affect neoplastic epithelium, and found that addition of excess pantothenic acid did not interfere with inhibition. Similar negative results with pantothenic acid were obtained in this laboratory.

To elucidate the tissue-differential effect of hexenolactone with respect to a possible mechanism involving alanine, several aquatic invertebrates were tested in media containing α-alanine, β-alanine, glycine, *iso*-leucine, *d*-glutamic acid or glutathione in addition to *M*/20,000 hexenolactone (that is, 0·0056 mgm./c.c. or one half the concentration needed to inhibit chick fibroblasts). Carefully matched control animals were cultured simultaneously in *M*/20,000 hexenolactone alone. The lactone was synthesized by McNeil Laboratories according to the method of Kuhn and Jerchel[2].

Best results were obtained with the flatworm *Dugesia tigrina*, which responds by developing a three-branched, *Y*-shaped lesion in the dorsal wall. The lesion corresponds in pattern to the triclad intestine. Extent of lesion is directly correlated with state of nutrition, being greatest in well-fed animals, regardless of body size.

The inhibitor, therefore, appears to take effect from within the animal, producing first a partial evisceration; secondly, disintegration of gut and surrounding mesenchyme; and lastly, the lesion in the dorsal epithelium. There is no antero-posterior susceptibility gradient, but a tissue-differential response. Measurements on lesion area, survival and extent of healing permit quantitative comparison between tests and controls. The following results represent percentage differences in lesion area, based on fifty-two separate experiments with a total of 2,010 specimens of *Dugesia tigrina*:

| | | | |
|---|---|---|---|
| | — 67·5 | per cent. | β-alanine *M*/40,000 |
| Protection | — 61·9 | ,, ,, | Glutathione *M*/50,000 (thio-alanine) |
| (reduced | — 46·8 | ,, ,, | β-alanine *M*/20,000 |
| lesion area) | — 46·3 | ,, ,, | Glutathione *M*/20,000 (thio-alanine) |
| | — 5·8 | ,, ,, | β-alanine *M*/5,000 |
| | + 2·4 | per cent. | *Iso*-leucine *M*/20.000 |
| No protection | + 18·6 | ,, ,, | *Iso*-leucine *M*/50,000 |
| (increased | + 29·6 | ,, ,, | Glycine *M*/40,000 |
| lesion area) | + 33·0 | ,, ,, | Glycine *M*/100,000 |
| | + 34·5 | ,, ,, | Glutamic ac. *M*/50,000 (*p*H adjusted) |
| | + 96·4 | ,, ,, | Glutamic ac. *M*/50,000 (*p*H not adjusted) |

Data on survival and wound-healing were consistent with these results. Only alanine and glutathione (the cysteine component of which is actually thio-alanine) had a specific protective influence. α-Alanine, tested on the annelid *Dero limosa*, behaved similarly to β-alanine. Glycine, *iso*-leucine and *d*-glutamic acid did not counteract the inhibitor but actually added to its toxicity.

Even the alanines ceased to give protection against *M*/20,000 hexenolactone at concentrations above *M*/5,000, although *M*/1,000 α- and β-alanine as such had no visible toxic effect. This seeming inconsistency with regard to concentration was obtained consistently not only with the alanines, but also with glutathione. Apparently the protective behaviour is confined to an optimum concentration within relatively narrow limits.

Since pantothenic acid does not interfere with the activity of hexenolactone, while α-alanine, β-alanine and glutathione (thio-alanine) do so, a specific alanine mechanism distinct from the alanine link in the biosynthesis of pantothenic acid is very probably at work in differential inhibition and differential tissue destruction by hexenolactone.

Mendez[4], studying digitalis- and angelica-lactones, found their cardiac activity dependent on peroxides formed in aqueous solution in the presence of metallic impurities. If the hexenolactone effect were likewise due to peroxide, protection by glutathione is feasible on the basis of a reaction between SH and $H_2O_2$. On the other hand, it is not clearly understood how alanine might behave toward peroxide, unless it gives rise to pyruvate upon oxidative deamination. If so, why should the hypothetical reactivity between alanine and peroxide decrease with a slight increase in the concentration of the former?

In view of the wide occurrence of simple unsaturated lactones and their probable function as natural

inhibitors, further work on their role in developmental and neoplastic growth should prove fruitful.

## Absolute Photopic Sensitivity of the Eye in the Ultra-violet and in the Visible Spectrum

IN a paper published in 1941[1], measurements of photopic and scotopic sensitivity were given; nine observers were used, after one hour adaptation to the dark, according to the method of colour appearance. These measurements were made in the range between the mercury lines 709 and 302 mμ. In this paper I am considering the question of absolute photopic sensitivity, as the inverse of the illumination of the retina $P_\lambda = 1/J_\lambda$.

The absolute photopic sensitivity, $P_\lambda$, in terms of number of (quanta/sec. sq. mm.)$^{-1}$ is related to the illumination of the pupil $E_\lambda$ (the latter being expressed in erg./sec. sq. cm.) by the equation

$$P_\lambda = \left[\frac{E_\lambda \times 10^{-2}}{h\nu} \cdot (1 - r) \cdot \frac{\sigma}{a}\right]^{-1},$$

where $r$ represents the reflexion losses at the cornea (assumed to be 0·05), $\sigma$ the area of the pupil (assumed to be 0·33 cm.$^2$) and $a$ the area of the image on the retina. The area of the image $a$ was 0·0083 mm.$^2$.

THE ILLUMINATION OF THE PUPIL, THE RETINAL ILLUMINATION AND THE ABSOLUTE PHOTOPIC SENSITIVITY OF THE NORMAL EYE IN THE ULTRA-VIOLET AND IN THE VISIBLE SPECTRUM (AVERAGE VALUES FOR 9 OBSERVERS).

| $\lambda$ mμ | $E_\lambda \frac{\text{erg}}{\text{sec. cm.}^2}$ | $P_\lambda \left(\frac{\text{quanta}}{\text{sec. mm.}^2}\right)^{-1}$ | Log $P_\lambda$ |
|---|---|---|---|
| 302 | $8 \cdot 47 \times 10^{-1}$ | $2 \cdot 16 \times 10^{-12}$ | −12·7 |
| 313 | $8 \cdot 86 \times 10^{-2}$ | $1 \cdot 87 \times 10^{-12}$ | −11·7 |
| 334 | $2 \cdot 13 \times 10^{-2}$ | $7 \cdot 75 \times 10^{-12}$ | −11·1 |
| 365 | $6 \cdot 69 \times 10^{-3}$ | $2 \cdot 25 \times 10^{-11}$ | −10·6 |
| 390 | $6 \cdot 84 \times 10^{-4}$ | $2 \cdot 10 \times 10^{-10}$ | − 9·7 |
| 404–407 | $1 \cdot 36 \times 10^{-4}$ | $1 \times 10^{-9}$ | − 9·0 |
| 435 | $1 \cdot 88 \times 10^{-5}$ | $6 \cdot 71 \times 10^{-9}$ | − 8·2 |
| 491 | $3 \cdot 35 \times 10^{-6}$ | $3 \cdot 34 \times 10^{-8}$ | − 7·5 |
| 546 | $1 \cdot 34 \times 10^{-6}$ | $7 \cdot 52 \times 10^{-8}$ | − 7·1 |
| 576–579 | $2 \cdot 74 \times 10^{-6}$ | $3 \cdot 47 \times 10^{-8}$ | − 7·5 |
| 690–709 | $4 \cdot 91 \times 10^{-4}$ | $1 \cdot 60 \times 10^{-10}$ | − 9·8 |

The accompanying table shows the results of my measurements of photopic sensitivity. The curve of photopic sensitivity has its maximum at about 546 mμ. A more exact determination of the maximum does not appear to be obtainable, as the mercury spectrum has no corresponding lines. In my paper[1] it is stated: "the chromatic sensitivity decreases regularly with the decrease of the wavelength to 302 mμ". Speaking strictly, the photopic sensitivity curve in the 365–334 mμ region has a small but still visible flattening, after which it drops abruptly again.

The *scotopic* sensitivity in this region has its maximum (in the case of some observers) or a pronounced flattening of the curve (in other cases). Apparently some maximum of transmission in the lens occurs in the region of 365–334 mμ.

Measurements of the photopic sensitivity curve in the ultra-violet were made by C. F. Goodeve (unpublished). These measurements clearly show a marked flattening of the curve and a point of inflexion at about 350 mμ.

Our results as concerns the character of the curve in the ultra-violet thus confirm the work of Goodeve *et al.*[2].

## New Light on the Mammalian Ear Ossicles

IN spite of many criticisms, the Reichert-Gaupp theory of the mammalian ear ossicles[1,2,3,4] has, in its main points, been confirmed by a considerable body of work on the developmental anatomy of recent mammals and reptiles, and on the structure of therapsid reptiles. There can be little question that the stapes, incus and malleus (except for its dermal component, the goniale of Gaupp) are essentially homologous respectively with the reptilian columella auris (proximal part or otostapes), quadrate and articular. The existence of vestiges of other elements of the reptilian lower jaw and extrastapes in the mammalian middle ear has been suggested by numerous investigators. Thus the goniale is usually equated with the pre-articular[1,2,3,4, etc.], and the elements of Paauw and Spence have been regarded as parts of the extrastapes[5]. But in general there has been little agreement on the detailed homology of the parts of the stapes, of the crura of the incus, and of the various processes of the malleus; this is largely because most of our information on these points is based on the anatomy of adult and embryonic stages of living mammals and reptiles, while mammals originated from the extinct therapsid reptiles, which differ from Lacertilia and *Sphenodon* in important respects. Until recently, too little was known in detail about the middle ear and lower jaw of therapsids, though Broom[6] showed the position of the tympanic membrane and the presence of an ossified portion of the extrastapes in some Therocephalia (see also ref. 7). E. C. Olson[8] has now provided, among other interesting things, an account of the structure of the otic region of several therapsids (Anomodontia, Therocephalia, Gorgonopsia, Cynodontia) based on serial sections. The structure of the middle ear region is greatly illuminated by this work; but some of his conclusions seem to be open to question, while others can be further supported.

In all the forms discussed by Olson the stapes is perforate, and has a well-marked articulation with the quadrate (by a "processus internus" meeting a special extrastapedial process or lamina from the quadrate), and a strong process which is clearly the base of the distally cartilaginous extrastapes. A processus dorsalis and a separate hyoid process are not present in the fossils. The quadrate in all forms lies in a deep groove in the squamosal, but seems to have been attached to the squamosal and otic region by connective tissue and ligaments only. Valuable new details of the lower jaw are also provided by Olson's sections.

The stapes is exceedingly mammal-like in character: it might be added that a columelliform stapes is present in some therapsids as well as in the adults of some Marsupialia and the Monotremata. It seems highly probable that the stapedial muscle was inserted on the posterior part of the therapsid stapes, probably on the processus extrastapedialis. The

position and relationships of Paauw's cartilage[5] now show clearly that this element is homologous with the proximal part of the extrastapes, and the processus internus of the therapsid stapes is as clearly indicated as the homologue of the head of the mammalian stapes. Olson, following van der Klaauw[5], seeks the equivalent of the processus internus in Spence's cartilage, and is driven to the conclusion that the incudo-stapedial articulation in mammals has shifted proximally on the stapes. But the relationships of Paauw's cartilage show that the mammalian articulation is the primary one, and Spence's cartilage needs further consideration. If it is not a structure peculiar to mammals, it can only be regarded as the remains of the distal (tympanic) portion of the extrastapes. Its position in mammals is quite consonant with this interpretation, and with the views previously expressed[7] on the evolution of the mammalian middle ear. The recent suggestion of Findlay[9], that Spence's cartilage and the manubrium mallei together represent the distal part of the extrastapes, is improbable in view of the developmental evidence that the manubrium is part of the mandibular arch, and of the nature of the therapsid retro-articular process.

Olson also criticizes Gaupp's recognition[1] (now widely accepted) of the goniale (dermal part of the processus Folii or gracilis of the malleus) as the reptilian prearticular. On the basis of the position of the goniale, partly lateral to Meckel's cartilage in some forms, and of variations in the course of the chorda tympani in mammals, he suggests that the goniale and tympanic annulus *together* are equivalent to the reptilian angular. This suggestion receives further support from consideration of the effects of the inward rotation of the lower part of the tympanic ring in many mammals. The ossiculum accessorium malleoli of some mammals (not discussed by Olson) also helps to confirm Olson's views. This small element lies medial or dorso-medial to the goniale, with which it often fuses, and medial also to the chorda tympani. Older investigators (see van Kampen[10]) speak of this bone lying *above* Meckel's cartilage, and it was regarded as the surangular by Watson[11]. Broom[12] and Forster Cooper[13] held the same view about a similar ossicle in *Chrysochloris* which, however, lies ventro-medial to Meckel's cartilage. The last-mentioned ossicle is almost certainly the prearticular; that of many Ungulates is probably the same, and may owe its position to rotation of the malleus and neighbouring lower jaw elements. This region deserves further investigation.

It is hoped to present a fuller account of this subject, with comments on recent work, in another place.

## Control of Buried Viable Weed Seeds by Means of Boron

BORON compounds, when present in the soil in abnormal concentrations, are known to exert a highly toxic effect on the vegetation. The extent of the toxicity at given concentrations varies according to the component species present in the vegetation, and according to the nature and texture of the soil[1].

In the course of an investigation conducted at the Welsh Plant Breeding Station to study the growth of red clover on old grassland soils, it was revealed that an application of borax at the rate of 90 lb. per acre had an extremely toxic effect on the germination and establishment of the clover. The soil was a medium loam of average fertility, and had carried grass vegetation for many years. The soil samples were taken at a depth of 2–6 in. below the surface vegetation, and placed in wooden boxes 21 in. × 15 in. × 3 in. Each treatment was replicated twice.

As was expected, the control boxes showed that the soil contained a very large population of buried viable weed seeds (see table below), but where borax had been applied at the above rate, a practically weed-free surface was obtained. The few weeds that did appear in the treated boxes were largely confined to the corners and around the edges of the boxes, where the distribution of the borax had presumably not been quite uniform.

The accompanying table shows the germination and establishment of red clover (sown at the rate of 35 seeds per box) in the treated and untreated boxes. The establishment figures of viable weed seeds are also given.

| | Germination | | Establishment | |
|---|---|---|---|---|
| Seedlings | Treated | Untreated | Treated | Untreated |
| Clover | 10 | 29 | 7 | 28 |
| Weeds* | — | — | 15 | 137 |

* The establishment figures given bear no relation to total buried viable weed seed population, as they refer only to such seed as were sufficiently near the surface to give visible seedlings.

It was evident from the fact that the surface obtained in the treated boxes was practically free from weed and clover that the toxicity of the borax had effected a very heavy kill on both the clover and buried weed seeds prior to their becoming visible seedlings.

The duration of the toxicity due to boron was further investigated and the treated boxes were resown with red clover at the previous rate (35 seeds per box), 35 days from the application of the chemical. The germination was now even and vigorous, and 31 seeds out of 35 gave strong normal seedlings. The germination of weeds was very low—only 15 weed seedlings appeared, and that in spite of the fact that the soil had been completely overturned at re-sowing. This seems to indicate that the toxic effect had operated throughout the depth of the soil.

It is evident from these figures that the toxic effect had been practically removed after 35 days. No determination was made of the precise number of days after which germination gained normality. Further, as this experiment was conducted in boxes and under glass, it is not known whether the removal of toxicity would occur at the same rate under field conditions. Also it must be stated that the rate of application

is not suggested as optimum, and a higher or lower rate may be more efficacious.

The results given above were obtained as part of a more general investigation; a more detailed repetition of the section dealing with toxicity is intended, before precise practical application can be suggested. These results do, however, offer distinct possibilities of practical control for one of the most acute weed problems in agriculture.

## Mechanism of the Milling Shrinkage of Wool Fabrics

THE work of Speakman[1] and his collaborators has indicated that the felting or milling shrinkage of wool fabrics is primarily due to the scaliness of the fibres, but that in cloths of similar construction and composition the magnitude of the effect is determined by the ease of extension and the power of recovery of the fibres. The shrinkage of fabrics milled under comparable conditions is greater in acid and alkaline solutions than in water, and cloths may be rendered unshrinkable by treatment with reagents such as chlorine[2], caustic soda[3] or sulphuryl chloride[4]. These phenomena may be due to modification of either elastic properties or scaliness, and the experiments described in this note were designed to determine which of the two characteristics was more affected. A complete account of the investigation will appear elsewhere, but its main features are as follows:

Measurements of the scaliness of wool fibres in acid (0·1 *N* hydrochloric acid), water, and 2 per cent borax solution (*p*H 9·24) were made by the violin bow method of Speakman and Stott[5], and the results are summarized in Table 1.

TABLE 1.

| Medium | Scaliness |
|---|---|
| 0·1 *N* hydrochloric acid .. .. | 29·4 |
| Water .. .. .. .. .. | 23·5 |
| 2 per cent borax solution .. .. | 21·5 |

The scaliness increases with decreasing *p*H, and hence scaliness changes act in unison with the reduced ease of extension to increase the rate of milling of fabrics in acid solutions. The reduced scaliness in alkaline solutions, however, acts in the opposite direction to the increased ease of extension, and the superior milling shrinkage in alkaline solutions of *p*H 9·24 must be due solely to increased ease of extension, which is not accompanied by a loss of power of recovery of the fibre.

The role of scaliness in determining the shrinking properties of wool fabrics has also been demonstrated by measuring the scaliness and elastic properties of wool fibres treated with a 0·2 *N* solution of chlorine in carbon tetrachloride for various times. Parallel experiments in which patterns of cloth were chlorinated under the same conditions, and then milled to measure their shrinkage, were also carried out. The results are shown in Table 2.

It is evident that the loss in milling shrinkage is mainly due to a reduced scaliness of the fibres, for there is little change in the elastic hysteresis, and the increased ease of extension would result in an increased shrinkage. Since cloths which have been chlorinated for two hours are completely unshrinkable when milled in acid or soap, it appears to be unnecessary to reduce the scaliness of the fibres to zero in order to realize unshrinkability. Similar results have also been obtained on cloths and fibres treated with other reagents which render wool cloths unshrinkable. Whereas the scaliness, as measured by the percentage difference in friction, is reduced by chlorination, the actual values of the angles of friction increase, indicating greater adhesion between the fibres and the surface over which they slip. This increased adhesion is reflected in the greater strength of chlorinated yarns, for since the strength of individual fibres falls on chlorination, the superior yarn strength must arise from an increased adhesion between the fibres.

TABLE 2.

| Time of treatment (hr.) | % shrinkage after milling for 30 min. | % reduction in work to stretch in | | | % Elastic hysteresis in | | | (iii) Scaliness in | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|
| | | Water (i) | 0·1 *N* hydrochloric acid (ii) | 2% borax (ii) | Water | 0·1 *N* hydrochloric acid | 2% borax | Air | Water | 0·1 *N* hydrochloric acid | 2% borax |
| 0·0 | 35·0 | 2·7 | 38·0 | 0·8 | 53·5 | 40·0 | 62·2 | 15·8 | 23·5 | 29·4 | 21·5 |

## Halogenation in the Allyl Position

IN the last issue of the "Annual Reports of the Chemical Society"[1], F. S. Spring has directed special attention to the success of Ziegler and his collaborators[2] in substituting olefines in the α-methylene, or 'allyl position', by means of N-bromo-succinimide, and it has been claimed that this is a new reaction.

Whereas from the preparative aspect N-bromo-succinimide is obviously a valuable new reagent, halogen substitution in the α-methylene position to a double bond is but to be expected if the reaction is of the 'free radical' or 'atomic' type, as shown recently by E. H. Farmer and his colleagues[3].

The 'atomic' chlorination of *cyclo*-hexene to $\Delta^2$*cyclo*-hexenyl chloride by benzene diazonium chloride was reported by me in 1939[4], and in 1937 I had suggested tentatively that compounds containing the so-called 'positive halogens', as, for example, the N-halogeno-imides, were molecules which underwent neutral or 'atomic' bond fission in preference to ionic bond fission[5]. The work of Ziegler should be regarded as a definite confirmation of this hypothesis.

Reaction mechanisms involving the neutral bond fission of 'positive halogen' compounds should, however, be applied with caution, since chemical changes of this type are in general chain processes very much dependent for their success on the concentrations and energy-levels of the transient radicals[6], and on the non-polar character of the solvent used. Thus Kharasch and Priestley[7] have reported the occurrence of two distinct types of addition reactions between N-halogeno-imides and olefines, and the regular use by Ziegler of carbon tetrachloride as solvent may well be an essential factor in contributing to the success of the α-methylenic substitution[6].

## A Colour Reaction for Aromatic Amidines

Ekeley and Ronzio[1] have described a series of coloured compounds which are obtained when aromatic amidines are heated with glyoxal in alkaline solution. The reaction is complex, and the results are uncertain and dependent on the conditions employed. By heating with a very small amount of glyoxal at *p*H 9 in the presence of a borate buffer, the reaction is made much more sensitive and reliable, and is suitable for the quantitative estimation of amidines down to 1 in 100,000[2]. The buffer is made up from 4 gm. of boric acid neutralized in hot solution with caustic soda to *p*H 9, and diluted to 100 ml. The glyoxal reagent is a 0·5 per cent aqueous solution of glyoxal sodium bisulphite.

To a few millilitres of the suspected amidine solution (containing a few milligrams of amidine and roughly neutralized if necessary) is added about a millilitre each of buffer and glyoxal reagent, and the mixture is heated almost to boiling for a few minutes, or for ten minutes in a boiling water bath. A pink or magenta colour appears, which usually becomes redder in acid and bluer in alkaline solution. Maximum colour is obtained with about two molecules to one of amidine, and excess of glyoxal inhibits the reaction.

The reaction appears to be sharply specific for an unsubstituted aromatic amidine group. It is given by C-substituted benzamidines, naphthalene diamidine and nicotinamidine. Nearly fifty aromatic amidines have been tested and found to give the reaction. It is not given by aromatic amidines with one or two methyl groups on the nitrogen atoms of the amidine group. Benzamidrazone and phenyl acetamidine give a pale yellow colour. Guanidines, biguanides, amines or aliphatic amidines do not react.

The reaction products from some aromatic amidines fluoresce in ultra-violet light down to dilutions of 1 in 100 millions. Those from the diamidine series (for example, propamidine) are sparingly soluble, show no colour change with variation of *p*H, and do not fluoresce.

When the method had been in use for some time, Devine[3] published a process of estimation using the brown colour produced when an amidine is heated with a large excess of glyoxal in strong caustic soda. This has the disadvantages that the glyoxal reagent is unstable and must be made up daily; that the conditions of heating are difficult to reproduce exactly; and that the colour is unstable and must be estimated immediately. It is, however, not so sensitive to variations in the amount of glyoxal used as is the present method.

I wish to thank Dr. H. King and Dr. J. Walker for supplying the compounds.

## David Forbes and Guano Archæology

In a footnote to a brief communication made by Virchow in 1873[1] is a statement transmitted to him through Jagor and A. W. Franks, which seems to imply that David Forbes, the well-known geologist, owned or knew of wooden statuettes taken from the guano deposits of the Peruvian coast, depicting a man being bitten in the penis by a snake. This *motif* is known on certain Mochica ceramics[2], but otherwise appears to be absent from Peruvian iconography.

We are engaged in the collection of all available data on the archæology of the now exhausted Peruvian guano deposits. The available information strongly indicates that important chronological and climatological results may be expected from this neglected field. We are therefore anxious to trace any further references to the material known to Forbes, as no published figure of an object from the guano, exemplifying the *motif* in question, is known to us. If the objects could be identified and were accompanied by indications of locality and depth, they would probably provide an important addition to the very restricted series of authenticated finds of early Peruvian cultures in guano. David Forbes is known to have made extensive mineralogical, geological and ethnographic collections; but the fate of these and of his extensive manuscript notes, not mentioned in his will, are unknown to us. We should be most grateful for any information that would lead to the discovery of this or of any other guano finds.

# MEDICAL STUDIES IN BRITAIN

FROM time to time the *British Medical Bulletin* publishes articles by experts on the development of medical studies in Britain. The first of these, on the development of ophthalmology (*Brit. Med. Bull.*, 1, 100; 1943), was noticed in *Nature* (153, 383, March 25, 1944). The second, third and fourth have now appeared (*Brit. Med. Bull.*, 2, Nos. 5–6; 1944). The second is on the genetic aspect of disease, by Dr. Julia Bell; the third is on obstetrics, by Prof. James Young, of the British Postgraduate Medical School, London; the fourth is on oto-laryngology, by Dr. Douglas Guthrie.

Dr. Bell, beginning with a quotation from Hippocrates (400 B.C.) on the hereditary origin of epilepsy, briefly outlines the subsequent history of ideas on the hereditary nature of some diseases. What she tells us of Karl Pearson is interesting because she was his assistant during 1908–14. Her discussion of modern genetics is a valuable summary in the short space available of a complex subject. Fundamental features of this third period of her survey have been the conception of the gene and its localization in the chromosome, and the study of linkage. Work of this kind has, she says, a limited application to hereditary disease in man, but notable work has been done on colour blindness and hæmophilia. The work on blood groups has been among the most important of the single discoveries made. Dr. G. L. Taylor, Dr. R. R. Race and Dr. W. T. J. Morgan have explained this work in an issue of the journal which is devoted to the blood and some of its disorders (*Brit. Med. Bull.*, 2, Nos. 8–9; 1944). The collection of the pedigrees of disease continues, says Dr. Bell, and there can be few in Great Britain who are better qualified than she is to discuss this method of investigation. She also discusses genetic work on cancer and leukæmia. If it is not possible, she says, to stay the onset or course of disease or of a defect which is genetically determined, preventive measures, such as the discouragement of consanguineous marriages or voluntary sterilization of possible transmitters of such diseases, have been considered. Dr. Bell concludes that little is to be expected from the former method, and that the latter may be very wasteful. There is, she thinks, great promise in the work now being done in experimental genetics and embryology, but the results obtained by the study of relatively primitive organisms should be applied to the human species with caution. The selected bibliography which she gives is valuable.

Prof. James Young traces British midwifery back to the reign of Henry VIII, when, in 1540, the first British text-book on the subject appeared—a translation of Rösslin's book published in Hagenau in 1513. Little progress was made during the sixteenth and seventeenth centuries, when practitioners of midwifery were mostly the ignorant and illiterate midwives who called in the doctor "with his destructive instruments" in emergencies. But Paré, in France in 1550, discovered the value of podalic version, and from this Prof. Young dates the rise of modern obstetrics. Obstetric forceps, "one of the greatest and most beneficent of all obstetric discoveries", were invented about 1630–34, but they remained a close secret of the English Chamberlen family for more than a century. Their use did not become general until Chapman first described them in 1713. It was William Harvey who introduced a new intellectual spirit into the study of obstetrics, but he strangely failed to realize the truth taught by his teacher Fabricius that the child is born by the muscular action of the womb, insisting that it "attacks the portals of the womb" and gets out by its own efforts. Harvey and others, including the Chamberlen family, made improvements in the status and instruction of midwives, and some control of them was instituted.

Harvey and his friends emphasized that labour was a natural physiological process and did not favour interference until it was clear that it was necessary; and this idea dominated the British school of obstetrics throughout the eighteenth century. By the middle of this century the British school had made such progress that it led the world. The genius of William Smellie (1697–1763) earned for him the description as "one of the most important obstetricians of all times and all countries". Prof. Young gives an interesting description of the fight between the men and women midwives. It is only recently that the British midwife has been given by the Midwives Act of 1902 and subsequent legislation "a position of prime importance in the maternity organization of the country". With the nineteenth century came anæsthesia, antiseptic and later aseptic surgery, and the story of the control of puerperal sepsis, the contagious nature of which was suspected by Gordon in Aberdeen in 1795 and independently in 1843 by Oliver Wendell Holmes in America and by Semmelweiss in Vienna. The fact that a streptococcus was the cause was demonstrated by Pasteur in 1867. British bacteriologists have played a notable part in the prevention of obstetric contagion.

The rest of this interesting article deals with the history and present position of preventive aspects of obstetrics and with the recognition of obstetrics as a special branch of medicine. "Gynæcology," says Prof. Young, "is a creation of the nineteenth century." It dates from the work of Virchow and the creation of the microscope. In the same issue of the *British Medical Bulletin*, Dr. W. C. W. Nixon writes on nutrition and pregnancy and lactation, and there are valuable reviews of selected papers on subjects of obstetrical and gynæcological interest.

Dr. Douglas Guthrie's article on oto-laryngology takes us back to Fallopius, whose name is familiar to every first-year student of biology. Fallopius wrote in 1564 what was probably the first complete book on the ear. It was not until 1748 that Duverney, of Paris, demonstrated that the Eustachian tube was not a means of breathing or hearing, but simply a means of renewing the air in the tympanum. Willis, of Oxford, also known to students of biology and medicine as the discoverer of the 'circle of Willis' and other features of the nervous system, published in 1683 his treatise entitled "Two Discourses concerning the Soul of Brutes", in which he gave an account of the phenomenon of hearing better in a noise (paracusis Willisi) and told of a woman who, though she was deaf, could hear every word perfectly so long as a drum was beaten in her room; her husband kept a drummer so that he could talk to her.

During the eighteenth century two of the most important instruments used in oto-laryngology were invented, both by laymen. Guyot, a postmaster of Versailles, produced in 1724 a form of the Eustachian catheter, which he introduced through his own mouth in order to syringe his ear and so relieve his deafness. In 1854 the Parisian singing master and singer, Manuel Garcia, invented the laryngoscope in order to see the action of his own vocal chords. But

in the eighteenth century oto-laryngology was chiefly concerned with diphtheria, which was very prevalent and fatal then. The first hospital in the world to be devoted to diseases of the ear, the Royal Ear Hospital, was founded in 1816 by J. H. Curtis, an unqualified man who had a large practice in London. The subsequent history of oto-laryngology brings us to Joseph Toynbee (1815–60), the father of Arnold Toynbee, James Hinton (1822–75), also remembered as a philosopher, and Sir William Wilde, of Dublin (1815–76), the father of Oscar Wilde. Toynbee's beautiful dissections were preserved in the Museum of the Royal College of Surgeons until they were destroyed by enemy action in 1941.

Laryngology became a special branch of medicine in the middle of the nineteenth century and Sir Morell Mackenzie was the founder of modern laryngology. Another great laryngologist was Sir Felix Semon, a German pupil of Mackenzie's who settled in London. Semon was one of the last to practise laryngology before it became merged with otology. Nowadays developments in bronchoscopy and oesophagoscopy are extending the boundaries of the science of oto-laryngology; and speech and voice disorders offer a further field.

Dr. C. S. Hallpike, in another article in this issue of the *British Medical Bulletin*, discusses research in otology and Dr. E. H. Broome discusses the scope of speech therapy. Dr. Guthrie provides a second article, on "Pioneers in the Teaching of the Deaf". A discussion on the audibility of the radio voice at a meeting of the Royal Society of Medicine will interest lay readers who are habitual radio listeners. It is evident that the radio speaker has to deal with a complex problem. Mr. John Snagge said in this discussion that it is impossible to tell from gramophone records whether a speaker will be a success at the microphone, and also that the construction or lining of the walls of a room in which a broadcaster speaks has little effect on the reception of his voice by the distant listener. The quality of the voice is often more important than the speed of the speech.

Peripheral vascular disorders are the subject of a valuable article by Prof. J. R. Learmonth (*Brit. Med. Bull.*, 2, No. 7; 1944). This issue is devoted to the peripheral blood vessels and deals with arterial spasm, arterial injuries and injuries due to low temperature, such as frostbite. Fifteen photographs illustrate the article on the pathology of immersion foot. The study of these conditions is always an important one, but it is perhaps even more important in these times of war and air-raid casualties.

G. Lapage.

# DECIDUOUS CYPRESS (*Taxodium distichum*)

By ALEXANDER L. HOWARD

This beautiful tree, the only cypress which sheds its leaves in the winter, is far too little known and appreciated by those who possess it. In spring its light-coloured feathery leaves fall gracefully from the pyramidal shape of the tree; in summer the full effect of the foliage is different from anything else in the landscape; in autumn it reaches perfection, when the sprays turn a golden hue, almost reminiscent of a set piece in a firework display; and in winter its curious habit of growth attracts the eye, because of its weird, almost ghostly appearance.

It is known in the United States by the names of bald cypress, swamp cypress and Louisiana cypress, and according to Sargent "rarely 12 feet and generally 4–5 feet in diameter above the abruptly enlarged strongly buttressed usually hollow base", occasionally 150 ft. high, but in Great Britain the maximum height and girth recorded is 110 ft. by more than 12 ft.

It is to be found sparsely distributed over a wide area, generally by the banks of streams, rivers or lakes. While it can be reared apart from such positions, it is essentially a tree dependent upon water-ways. Introduced from other countries, it has both suffered and benefited by the fashion of the day. For the last half-century it has been almost forgotten, while in the beginning of the nineteenth century it was extensively planted, and a number of these trees are still flourishing to-day, but inquiries I have made seem to show that few, or perhaps scarcely any, have been planted during the last half-century. Interesting accounts of many fine examples are catalogued by Elwes. He mentions:

> "The trees at Syon have been frequently described and figured. They are planted in damp soil by the side of a sheet of water, and one of them has produced knees of 1 to 2 feet high. This tree . . . measured in 1903 90 feet by 12, but there is a much taller one on the other side of the water, which when we saw it last, in 1905, was 110 ft. high, and is the tallest we know of in Europe. Another, in the Duke's Walk, is 85 feet by 10 feet 3 inches."

In October 1944 I visited Syon and the trees were in perfect health. I was doubtful which one Elwes found to be 90 ft. by 12 ft., but I measured the largest, which exactly answered his description of site, and found it to be 21 ft. around the base. The knees rising to 2 ft. and a little more range around the tree on three sides—on the south side to 52 ft., on the west side to 46 ft., and on the north side to more than 40 ft. There is also on the other side of the walk a very handsome young tree about 80–90 ft. high and 12 ft. girth at the base.

Elwes also reports:

> "At White Knights, Reading, there are several trees, but none of large size, the biggest measuring, in 1904, 67 feet by 7 ft. 10 inches. They are remarkable, however, for variety of habit. One is a tall narrow tree with upright branches, almost fastigiate. In another tree the stem is twisted, as often occurs in the chestnut, and most of the branches are twisted also in the direction against the sun. Loudon mentions these as young trees of peculiar habits."

Mr. F. G. Franklin, at White Knights, writes to me under date of October 7, 1944, as follows: "the trees you mention are still alive but I could not say they are very much larger than you say."

And further:

> "At Strathfieldsaye there is a tree, mentioned by Loudon as being 46 feet in height by 3 ft. 4 in. in diameter, which I found in 1903 to be 63 ft. high by 9 ft. in girth (I have a letter from the Duke of Wellington in October 1944, in which he informs me this is now 69 ft. and the girth 11 ft. 6 in. at 5 ft.) It is growing in stiff clay soil and has no knees: the stem is deeply furrowed.
>
> "At Coombe Abbey, Warwickshire, Mr. W. Miller reports that a tree, mentioned by Loudon as 47 ft. by 2 ft. 3 in. (diameter e.d.) in 1843, had attained, in 1887, 75 ft. by 11 ft. 6 in. at 3 ft. from the ground. [In answer to an inquiry I am told by Mr. J. G. Gray there has been no such tree there for the past 22 years.]
>
> "At Brockett's Park, near Hatfield, there are many trees planted along a walk on the banks of the Lee, and

forming an irregular line in which the trees vary very much in size. In the sheltered part of the valley, where the soil and situation are very favourable, they average 70–80 ft. high, the best I measured being 80 ft. by 10 ft. and 86 ft. by 9 ft. But lower down the stream, where the valley is more exposed to the wind, they are stunted, and not more than half the height of those above. There are knees on some of the trees overgrown with moss and meadowsweet, but not so large as those at Syon."

I saw these trees in the autumn of 1943 and found them generally in good health, but some damaged by tempest.

In the courtyard of Dartington Hall, near Totnes, a very fine tree flourishes, and this was shown to me by Mr. Elmhurst a few years before the War. When I expressed surprise that this great tree stood alone in good health in an exposed position on the hill, he explained that its roots were in a large disused well. A similar tree is in good health to-day at the Grand Hotel, Lyndhurst, perhaps 70–80 ft. high, where it also is said to have its roots in a disused well. A fine tree about 70–80 ft. high and more than 2 ft. 6 in. in diameter grew by the side of the stream a little north of Hunton Bridge, near Watford, Herts. This may have been the tree which Elwes figures as being, when he measured it, 85 ft. by 14 ft. in 1884. At the request of the owner, about twenty years ago, I had it cut down: reference to the wood will be made later, but I heard a few years after that my brother had known the tree and had landed many good trout under its branches. The two dates of fashionable planting appear to be during 1720–62 and in 1843, and choosing between these without further information, I think this tree must have belonged to the earlier date. Inquiries over twenty years gave disappointing results, as few trees could be found of later planting. Some good specimens can be seen at the Pinetum at Bedgebury. Mr. W. Dallimore writes me under date of October 11, 1944, as follows:

"The Taxodiums at Kew are, I imagine, from 75 to 80 years old, although I cannot be certain on the point. The Taxodiums at Bedgebury are all quite young. Some were planted in 1926, others in 1927, and they were 3 to 4 years old when planted."

The varying habit of growth is characteristic of the tree in the United States, and it is the same in Great Britain. This feature is noticeable when the limbs are bare, and this ghostly appearance, previously referred to, stands out against the winter sky.

The wood is of great value, and so far much too little appreciated in Britain. Quoting from "Timbers of the World":

"It is imported in the form of planks and boards of various qualities, but only of late years in any considerable quantity. It is yellowish-red, often nearly salmon coloured. In the United States it is used so extensively that Gibson writes 'the uses are so nearly universal that a list is impossible'. Another American authority, Hough, says: 'Its great durability, immunity from the attack of parasites, and non-liability to great shrinking or warping makes it one of our most valuable woods for all woodwork exposed to weather, for tank construction, cooperage, etc.'. These qualities combined with a sharp segregation of the hard and soft grain, and with a scantiness of resin, should bring this wood into more general use. It is especially satisfactory for out-houses and green-houses, and where so used will probably outlast any other kind of softwood, even when unpainted. One such unpainted building in this country has survived for six years (1920), and the wood, though subject to continual heat and moisture, is quite sound throughout. [Inquiry to-day (1944) shows that the woodwork in the orchid-houses referred to is in perfect condition, without showing any sign of decay.] The English grown wood appears to possess equally good qualities, and where available should be used for exposed woodwork. It differs from the American grown timber that reaches this country in colour, which is light yellow, and in appearance it recalls Lebanon cedar. . . ."

Gibson has made a statement which suggests that the remarkable durability of this wood is somewhat doubtful, but there is reason to question his opinion. Prof. C. S. Sargent, in a private letter (March 3, 1915) on this subject, says:

"The wood (*Taxodium distichum*) is considered to be exceedingly durable, and I do not know on what authority Gibson has made his statement. It is not impossible, of course, that the wood of a diseased tree, or one that had grown under abnormal conditions, might be of poor quality."

A very large quantity was purchased by the British Government during the War for aeronautical construction, but it was found to be unsuitable, and led to deplorable results.

Its great durability renders it most valuable, but the foregoing is an illustration of the undesirability of accepting a timber based upon mechanical experiments, and lends a strong argument in favour of following the advice of the unprejudiced craftsman.

This tree, not indigenous to Great Britain, should be planted wherever possible, for its great beauty and utility: it must be borne in mind, however, that in its native habitat it grows in close proximity to streams or abundant water supply.

## NORTH AMERICAN ARCHÆOLOGY AND CULTURES

BULLETIN 133 of the Bureau of American Ethnology (Washington, D.C.: Gov. Printing Office. 1 dollar) includes seven Anthropological Papers (Nos. 19–26) of varying importance, dealing with the American Indians and their cultures.

Dr. P. Drucker contributes a useful survey of northern North-West Coast archæology, which, in contrast to the ethnology of the region, has been much neglected. The paper is based on his own field-work on a number of middens in the country occupied by the coast Tsimshian and Kwakiutl in historic times, supplemented by a summary of previous publications and museum collections. No marked difference is apparent between the cultures excavated and those of the recent tribes, but Dr. Drucker believes that some kind of culture sequence will yet be found, on the analogy of neighbouring areas. Finally, it is suggested that both archæological and recent cultures of the northern North-West Coast fall into three main geographical divisions, described as the northern (Tlingit-Haida-Tsimshian), the Milbanke-Queen Charlotte Sound (Kwakiutl), and the Straits of Georgia-Puget Sound aspects.

A large part of the volume is occupied by a study of the Eastern Cherokees of North Carolina by W. H. Gilbert, jun., based on two years of research which included a four-months sojourn among them. A survey of the culture of this remnant is followed by a description of the state of the tribe in former times, culled very largely from MS. data collected by J. H. Payne in the first half of the nineteenth century. Comparison between the two periods shows not only

the inevitable impoverishment of culture caused by contact with the white man, but also certain fundamental changes. The social organization of the older society, with its white and red officials for peace and war, conforms in general with that of other south-eastern tribes. The surviving remnant has lost this dual division, and has developed other features of which the most striking is a system of preferential mating; this has become linked with the matrilineal clans to which most members of the tribe still belong. The essence of this is that a person is expected to marry into one of his grandfathers' clans, but not into those of his parents, a state of affairs which was happily expressed by an Indian informant who said, "The Cherokees marry their grandmothers!" This system is unparalleled anywhere outside Australia, and its appearance is used to point the moral that a study of the historical antecedents of a tribe will not necessarily throw light on its present-day organization. A feature of this paper is a series of elaborate family-tree diagrams.

Another paper on the social and religious life of a dying Indian society deals with the Carrier Indians of the Bulkley River basin in British Columbia. It is contributed by D. Jenness, who spent about four months among them. A good account is given of the political organization, including the part played by clan and personal crests, and there is a brief summary of the life-cycle. The section on religion includes an interesting account of some hybrids formed by the impact of Christianity on the old beliefs, and the importance of dreams in the religious life of the people is stressed. The remarkable lack of historical sense among these people is shown in the impossible stories which they weave around events scarcely a generation old. The paper ends with an account of the medicine men, which includes a remarkable first-hand description of a ceremony for the cure of 'kyan sickness', a kind of hysteria involving cannibalistic cravings, to which these Indians seem particularly susceptible.

A paper by Robert F. Heizer on "Aconite Poison Whaling in Asia and America" gives a survey of whaling along the North Pacific coasts from Japan to Vancouver Island, which shows that three basic methods were practised. Netting is found mainly in Japan, the harpoon-line-float method is practised by the Eskimo and Chukchee in the Far North and is also found in the Vancouver - West Washington area, and spearing with a lance dipped in aconite poison predominates in the intermediate regions of both Asia and America. It is concluded that the poisoning method was used first by the Ainu and by the Kamchadal of Kamchatka, whence it is conjectured that it spread to the Aleutian Islands and the neighbouring part of the mainland of Alaska. It is probable that the movement was in this direction, but a word of caution is necessary since the link between the two areas is weak at its western end, because evidence for the ancient occupation of the Commander Islands is lacking.

In "The Quipu and Peruvian Civilization", John R. Swanton, arguing from quotations from the chroniclers, concludes that the quipu was used as a more extensive method of expression than the mere recording of numbers. From analogy with other high civilizations, he considers that Andean culture must have had such a mode of expression—a singularly unconvincing argument. It is suggested that the most highly developed quipus are likely to have been in public repositories which the Spaniards destroyed.

# FORTHCOMING EVENTS

## Saturday, December 16

PATHOLOGICAL SOCIETY OF GREAT BRITAIN AND IRELAND (joint meeting with the BIOCHEMICAL SOCIETY) (at the Royal Society of Medicine, 1 Wimpole Street, London, W.1), at 11 a.m.—Discussion on "Cancer".

NORTH OF ENGLAND INSTITUTE OF MINING AND MECHANICAL ENGINEERS (at Neville Hall, Newcastle-upon-Tyne), at 2.30 p.m.—Mr. D. MacFarlane: "Mine Ventilation with reference to Fan Types and their Application".

QUEKETT MICROSCOPICAL SOCIETY (at the Royal Society, Burlington House, Piccadilly, London, W.1), at 2.30 p.m.—Dr. W. S. Bristowe: "In Quest of Spiders".

## Monday, December 18

ROYAL GEOGRAPHICAL SOCIETY (at Kensington Gore, South Kensington, London, S.W.7), at 8 p.m.—Mr. and Mrs. Harold Ingrams: "Hadhramaut in Time of War".

## Tuesday, December 19

ROYAL ANTHROPOLOGICAL INSTITUTE (at 21 Bedford Square, London, W.C.1), at 1.30 p.m.—Dr. O. Samson: "The Place of China in an Ethnographical Museum".

ROYAL SOCIETY OF ARTS (DOMINIONS AND COLONIES SECTION) (at John Adam Street, Adelphi, London, W.C.2), at 1.45 p.m.—Dr. I. E. Coop and Mr. A. L. Poole: "Scientific Collaboration between the United Kingdom and New Zealand in War and Peace".

EUGENICS SOCIETY (at the Royal Society, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Discussion on "Aspects of the Housing Problem" (to be opened by Mr. Alexander Block).

ROYAL INSTITUTION (at 21 Albemarle Street, Piccadilly, London, W.1), at 5.15 p.m.—Sir Henry Dale, O.M., G.B.E., Pres.R.S.: "Modern Developments in Chemical Therapeutics", (iii) "Penicillin and Antibiotics".

INSTITUTION OF ELECTRICAL ENGINEERS (RADIO SECTION) (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Discussion on "The Television-Receiver Sound Channel" (to be opened by Mr. D. C. Espley).

## Wednesday, December 20

ROYAL SOCIETY OF MEDICINE (at 1 Wimpole Street, London, W.1) at 2 p.m.—Discussion on "The Principles and Relationships Involved in Medical and Veterinary Education" (to be opened by Sir Henry Dale, G.B.E., O.M., P.R.S., Prof. J. B. Buxton and Prof. G. W. Pickering); at 4.30 p.m.—Dr. J. D. Rolleston: "The Folk-lore of Toothache" (C. E. Wallis Lecture).

INSTITUTION OF ELECTRICAL ENGINEERS (LONDON STUDENTS' SECTION) (at Savoy Place, Victoria Embankment, London, W.C.2), at 7 p.m.—Mr. J. F. Stirling: "The Condensation of Atmospheric Moisture on Insulation Surfaces".

## Friday, December 22

NORTH-EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS (in the Lecture Theatre of the Literary and Philosophical Society, Newcastle-upon-Tyne), at 6 p.m.—Dr. H. Orenstein: "Methods and Motion Study Applied to the Shipbuilding Industry".

ASSISTANT TO THE ADVISER IN MYCOLOGY for the Western Province under the scheme of the Ministry of Agriculture and Fisheries—The Principal, Department of Agriculture and Horticulture, Long Ashton, Bristol (December 28).

AGRICULTURAL TRAINING OFFICER to organize the training in Agriculture and Horticulture of men and women released from War Service—The Executive Officer, Kent War Agricultural Executive Committee, County Hall, Maidstone (December 30).

DEPUTY CITY ELECTRICAL ENGINEER AND MANAGER—The Electrical Engineer, Electricity Works, Peterborough (endorsed 'Application for Deputy Electrical Engineer') (December 30).

ASSISTANT TO THE ADVISORY CHEMIST, Department of Agriculture—The Secretary, School of Agriculture, Cambridge (December 30).

ORGANIC CHEMIST on the staff of the Council for Scientific and Industrial Research, Division of Industrial Chemistry—The Secretary, Australian Scientific Research Liaison Office, Australia House, Strand, London, W.C.2 (December 31).

LECTURER (full-time) IN ENGINEERING in the Ashington Mining School—The Director of Education, County Hall, Newcastle-upon-Tyne 1 (December 31).

SENIOR LECTURER IN AGRICULTURE, and a BURSAR—The Clerk to the Governors, Royal Agricultural College, 7 Dollar Street, Cirencester (January 1).

TECHNICAL ASSISTANT IN THE HULL ELECTRICITY DEPARTMENT—The General Manager, Electricity Offices, Ferensway, Hull (January 1).

INSPECTOR OF AGRICULTURE, Sudan Government—The Ministry of Labour and National Service, Central (T. and S.) Register, Room 5/17, Sardinia Street, Kingsway, London, W.C.2 (quoting Reference No. F.3285.A) (January 2).

CHIEF ENGINEER of a large factory in Lancashire which, though not making machinery itself, uses a wide variety of machinery in its own processes—The Ministry of Labour and National Service, Central (T. and S.) Register, Room 5/17, Sardinia Street, Kingsway, London, W.C.2 (quoting Reference No. C.2384.XA) (January 8).

SENIOR PROFESSIONAL OFFICER (temporary), Industrial Diamond Research, University of the Witwatersrand, Johannesburg—The Secretary, Universities' Bureau of the British Empire, c/o University College, Gower Street, London, W.C.1 (January 15).

ASSISTANT LECTURER (Grade III) IN THE DEPARTMENT OF ZOOLOGY—The Registrar, The University, Liverpool (January 20).

ASSISTANT IN THE DEPARTMENT OF ZOOLOGY—The Registrar, The University, Liverpool (January 20).

CHAIRS OF POLITICAL ECONOMY AND ENGINEERING—The Secretary, The University, Aberdeen (March 31).

LECTURER IN GEOGRAPHY—The Secretary, The University, Aberdeen (March 31).

JUNIOR LECTURESHIP IN CHEMISTRY—The Secretary, Queen's University, Belfast (April 30).

TEACHER (man or woman) qualified to teach SCIENCE and MATHEMATICS in the Junior Technical and Day Continuation School—The Organizer of Further Education in Rugby, College of Technology and Arts, Eastlands, Rugby.

LECTURER (full-time, man or woman, temporary) IN BIOLOGY in the Leeds College of Technology—The Director of Education, Education Offices, Leeds 1.

ASSISTANT MASTER to teach MECHANICAL ENGINEERING Subjects—The Principal, Technical College, Wolverton, Bucks.

GRADUATE TEACHER (full-time) OF ENGINEERING for Day and Evening Classes in the Crewe Technical College—The Director of Education, County Education Offices, City Road, Chester.

ELECTRICAL OR MECHANICAL ENGINEER (Graduate or with equivalent qualifications) to teach ENGINEERING DRAWING, ENGINEERING SCIENCE, or MATHEMATICS, in the Maidstone Technical Institute—The District Secretary, Kent Education Committee, 13 Tonbridge Road, Maidstone.

GRADUATE LECTURER IN MECHANICAL ENGINEERING, mainly for Junior Day Work with some Senior Full-time or Part-time Day and Evening Classes in the Southend Municipal College—The Chief Education Officer, Education Office, Warrior Square, Southend-on-Sea.

## DEMOBILIZATION AND THE ALLOCATION OF MAN-POWER

THE debate in the House of Commons on November 16, although taking place before the appearance of the second White Paper on the Re-allocation of Man-Power—that dealing with civilian employments—made it clear that, subject to one criticism, the scheme outlined in September for the re-allocation of man-power between the Armed Forces and civilian employment during any interim period between the defeat of Germany and the defeat of Japan (Cmd. 6548. London: H.M. Stationery Office) went far to meet the desiderata laid down in the various statements and reports on demobilization that had previously appeared. Mr. Bevin's speech in particular showed that in its proposals for the orderly unwinding of the man-power of the country, the Government has had the closest regard to such suggestions. It was equally clear from speech after speech that the proposed arrangements met the crucial test almost invariably proposed in such reports: they are readily understood and accepted as fair in the Forces. The debate itself should help to carry that understanding and acceptance a stage further; for no one who followed it could have any doubt as to the Government's determination that there should be no evasion of the principles laid down, or of the support from all quarters of the House for the view that only on the clearest grounds of public interest should there be any exception to the order of release laid down.

The one major criticism or reservation was that insufficient consideration was given to the claims of men who had served for a long period overseas without home leave. Those claims were pressed on the Government with great skill, sincerity and force, not merely by several serving members but also by others, sometimes perhaps with a zeal which tended to overlook the fact that what was under debate was not demobilization in the true sense, but as the White Paper emphasizes, the re-allocation of man-power. "General demobilization," it is emphasized, "either of the Armed Forces or of war industry, cannot take place until the end of the war against the Axis Powers and their total defeat throughout the world." The Government's plan is framed on the basis that hostilities will end first in Europe, and it relates solely to the interim period between the defeat of Germany and the defeat of Japan. It is governed by the paramount consideration that there can be no break in the war effort after hostilities cease in Europe, and that in association with the other Allied Powers at war with Japan there must be the maximum deployment of the forces needed to bring complete and final victory at the earliest possible moment.

It is, of course, true that if demobilization plans are to be understood and accepted as fair in advance, above all by those most concerned, namely, members of the Forces, they must be prepared and explained long before hostilities come to an end. Any misunderstanding on this point should be removed by

the Prime Minister's firmness and explicitness ; but his subsequent announcement on November 17 of the new scheme for a system of short home leave for troops serving overseas goes some way to meet the major reservation in the welcome given to the re-allocation scheme. There are, however, other considerations of special interest here, not all of which were noticed in the debate on November 16.

That debate was under some handicap in proceeding before the publication of the second White Paper (Cmd. 6568. H.M. Stationery Office, November 1944, 2*d*. net.), and before discussing these particular points the two schemes must be briefly summarized. As an essential part of the re-allocation of man-power, the first scheme proposes to continue the compulsory recruitment of men for the Forces in order to bring relief to the men who have served for long periods and enable more of them to return to their homes. It will also be necessary to maintain the requisite control over industry and labour during the interim period, in which there will continue to be heavy and over-riding demands for munitions of war and other essential production.

Until the requirements for the continuation of the war against Japan and for the garrisoning of occupied countries are finally known, the level at which the Armed Forces must be maintained cannot be determined precisely. While re-allocation between the Armed Forces as a whole and industry will clearly be possible on a substantial scale, the Government affirms that military requirements must over-ride all other considerations. The arrangements must also not be too complicated for practical application, and the Government takes the view that a fair and reasonable scheme can best be secured on the basis of release according to age and length of service. It will also be necessary to make limited provision for certain urgent work of reconstruction on which a beginning must be made in the interim period.

The plan accordingly provides for two separate methods of selecting men for return from the Forces. Class *A* will be selected according to age and length of service ; Class *B* on account of their qualifications for urgent reconstruction work. No man will be released or transferred from the Forces if his retention is considered necessary on military grounds, though the Services will make every effort to release men in their turn in whatever theatre of war they may be serving. Men due for release or transfer will be given an opportunity to volunteer for a further period of service.

The number of releases in Class *A* will correspond with the reduction in the strength of the Forces and will be increased in consequence of the calling up of further recruits. Except that men of fifty years of age and more will be treated as a priority class to be released first if they so desire, men will be released by a combination of age and length of war service, on the basis that two months of service is equivalent to one additional year of age. Release will commence as soon as practicable after the defeat of Germany.

The men in Class *B*, who will be specially transferred from the Forces, will be those identified as belonging to particular occupational classes specified by the Minister of Labour and National Service as required for certain urgent reconstruction employments. The Class will also include a limited number of individual specialists, for whose transfer application may be made through Government departments in accordance with existing arrangements. The transfers in this Class will be few compared with the releases in Class *A*, and the number will be determined from time to time by the immediate requirements for reconstruction, and the extent to which those requirements will be met by releases in Class *A* and by transfer from munitions and other work at home. The men will be liable to be recalled individually to the Forces if they discontinue their reconstruction employment.

Further principles regarding re-allocation are laid down in the second White Paper, on re-allocation of man-power between civilian employments, which itself refers to some of the points made in that dealing with Employment Policy (Cmd. 6527. London : H.M. Stationery Office). The task will be to ensure that our limited resources are concentrated first upon those munitions required for the Armed Forces, and, secondly, upon those products which are most important to national recovery and to an improvement in the standards, not of those who can pay the highest prices, but of the community as a whole. The existing system of allocating man-power to the Forces and to the various industries, based on the annual man-power budget and carried out under the present system of priorities, will be continued. It is believed that the only way to avoid serious dislocation and dissipation of our resources on objects of secondary importance, and the production, so far as practicable, of necessities rather than luxuries, is to re-allocate man-power during this interim period on such a planned basis with some control over industry and labour, in accordance with certain established broad principles.

In the man-power sphere the aim must be to seek to mitigate the severity of the existing labour controls, to pay all possible regard to the natural desires of workers to seek work where they please, and of employers to engage labour freely, and to ensure that the workers which are available are employed in the places where, and on the tasks which, they are most needed in the national interest. Accordingly, the Government's policy endeavours to meet such wishes, especially that to return home, so far as is consistent with due regard for the general well being of the country. Subject to the same over-ruling consideration, it will also be the aim to transfer experienced workers back to their former industries. Release of persons in civilian employment cannot be determined purely by redundancy ; over-riding priority will be given to certain classes who, on personal grounds, have a claim for specially sympathetic treatment in the matter of release for retiring from industry or to work nearer their homes.

When these priority classes have been released some establishments, mainly in the munitions industries, will still have redundant labour, while other

establishments will be requiring labour. The problem therefore becomes one of transfer of labour, with some of the vacancies of greater importance than others; and in this redistribution of labour it is proposed that, apart from the call-up for the Forces, the two main classes to be released first should be those needed for priority vacancies and those who have worked away from home for more than one year and want to return.

As regards men for the Forces, all men in the age groups 18–27 will be liable for calling up; but those in the range 25–27 will only be called up if there are insufficient men in the lower age-ranges to meet requirements. Deferments will continue to be granted for men with special skill. In the selection of workers for transfer to priority vacancies under redundancy, existing selection procedure, which includes consultation with representatives of employers and workers, will be followed, and a major objective will be to transfer as many persons as possible back to their homes. The priority orders will also be applied where necessary to the transfer of workers to industries which need to maintain or increase their labour force. Registration of young men and women for employment or national service will be continued.

While the Government's proposals aim at effecting the necessary redistribution of man-power on a voluntary basis as far as possible and at narrowing the field of compulsion to the strictest limits, a substantial measure of control over the movement of labour must be retained. The Government desires both to give employers as much freedom as it can in the engagement of workers, and to ease the position of as many classes of workers as possible, especially in the older age groups. Controls over juveniles are to be considered in relation to the whole question of juvenile employment and a separate scheme is being worked out in consultation with the interests concerned, the paramount object of which will be to assist juveniles to the maximum extent possible in the choice of employment with the view of giving them the best opportunities for a permanent and progressive career in life with due regard to individual aptitudes.

It is on this question of education and training that criticism of the two schemes as a whole may well centre. The Government recognizes explicitly that the position of those young people returning from the Forces, who have the first claim to resume their education, must be safeguarded, but neither in the debate nor in the White Papers are the full implications of this policy indicated. The significant omissions are references to the release of teachers, and particularly university teachers, and of students to resume their studies.

That the Government has made no pronouncement on this point is the more important because the case for concessions rests entirely on national grounds. It is supremely important that there should be full and widespread public appreciation of the necessity for Government action, and no room for misrepresentation as favoured treatment for a particular class. Moreover, the demobilization of students of itself will be wasteful unless their release is timed with a view to resumption of their studies at the beginning of a course. Such demobilization, from the national point of view, calls for consideration as part of a national policy for youth, in which registration for national service and liability for enlistment in the Armed Forces must be placed in the long-term perspective in relation to educational policy. A decision on the question of a year or other period of national service as part of our national system must be taken at an early date. The Civil Service National Whitley Council has done well to direct attention to this point in its recent report on the staffing of the Civil Service during the reconstruction period.

The importance of higher education may well need some careful and painstaking explanation to the general public before its bearing on the national welfare is understood. Men released from the Forces cannot be accepted for re-training or for university study unless those required to instruct them are previously released from Government service; further, our whole expansion of scientific and industrial research depends on the orderly demobilization and re-allocation of scientific man-power, in which the release of teachers must have a high priority if the recruits required for industry itself are to be available in three or more years time. It must be remembered that for five years practically no male students have taken a university degree except in medicine and certain scientific subjects. Before the War, Sir Richard Livingstone has pointed out, British universities were training barely enough men for the national needs. In these last five years, except for the small fraction exempted from national service for reasons of health, they have been producing no graduates in subjects of such obvious immediate practical necessity to national life as economics, modern languages and the social sciences, in mathematics, history, law, literature, philosophy; and very few in scientific subjects such as botany, geology, and zoology.

While this gap remains, there will of necessity be grave weaknesses in the Civil Service, the professions, the executive ranks of industry and commerce, and the cultural life of the nation as a whole. The closing of this gap is one of the most important reasons for university expansion, and however swiftly the problems there may be solved and however generous the Government's contribution on the financial side, it will take time to close the gap. The men and women of trained capacity so urgently needed in every branch of the national life cannot be produced to order: three years are required for graduation, and several years more for competence in handling public affairs.

Release for this purpose is clearly a complicated question; only those with very special qualifications as students, such as holders of open scholarships, and men and women who have proved themselves first-class teachers, could be considered for priority release. It is all the more important, therefore, that from the national point of view there should be the minimum interruption of studies consistent with the demands

for the prosecution of the War itself. The longer those students who have been called up before completing their courses remain with the Forces, the more wasteful the interruption is likely to be from an educational point of view. Equally, it is important that there should be no further interruptions unless absolutely essential.

It is at this point that, as indicated in three of the articles contributed to the special number of *The Political Quarterly* dealing with the future of the universities, the report of Lord Hankey's Committee is so important. Any preferential demobilization of teachers or university students in Class *B* must clearly be based on the quantitative findings of that Committee as to the probable demand for graduates, and must be related also in some measure to the short-term and long-term development of the universities. Moreover, whether or not the pre-war student population represented, as Dr. Cyril Burt's article suggests, the right proportion of our population qualified to profit by a university education, it is certain, as Sir Lawrence Bragg's article indicates, that not all those best qualified have in fact been included. Apart altogether from Sir Ernest Simon's contention that we have as yet no real evidence as to the proper proportion of the population which is worthy of a university education, the demobilization scheme offers an undoubted opportunity, not only of removing an important bottleneck in reconstruction plans, but also of returning to the university, to the national advantage, some of those promising youngsters of outstanding judgment and intelligence as shown in their record of war service, who through economic or similar reasons have fallen off the educational ladder before reaching the university.

Clearly it might be inequitable to exempt all university students as a class, but the liability to military or other form of national service might well be enforced before or on completion of their university training in accordance with a deliberate national policy on the lines suggested in the Norwood Report and the reports of the British Association Committee on University Education and other bodies. This consideration was not very evident in the debate in the House of Commons on November 16, although Mr. Bevin indicated the Government's acceptance of the view that we must get our educational system going again as soon as possible. Nor was there any reference in the debate to the fact that demobilization of teachers must clearly proceed in stages rather than as one group, in order that the schemes for educational training in preparation for demobilization already announced by the Army and the Royal Air Force (see *Nature*, **154**, 525; 1944) may not be deprived of the instructors and potential instructors necessary for them to function.

Apart from this, the problem of education and teachers in relation to demobilization was fairly raised in the debate by Prof. Gruffydd, who not only made the point of priority in regard to the national needs—though that might have been more forcibly put—but also rightly directed attention to the age factor: the age-level is rising because we cannot get new lecturers, and if anything is important for reconstruction and for new ideas in the country, it is that the university teachers should be young men with young ideas. Mr. Bevin's reply was satisfactory so far as it indicated the Government's appreciation of the seriousness of the position. It may be doubted whether as large a number will be due for release for the universities in Class *A* as he suggested, and few of those thus scheduled will meet Prof. Gruffydd's criterion on the ground of age. Mr. Bevin stated, however, that the Minister of Education and the Secretary of State for Scotland are ascertaining from the local authorities how many teachers they would get back under Class *A*, and that the Government would then see what number is necessary for the schools and also for the universities.

This is undoubtedly the soundest line on which to proceed to establish the case for release on national grounds; but while that quantitative inquiry is proceeding, every effort should be made, both by the Government and by other authorities, to make sure that public opinion fully understands what is involved and the national reasons for priority. There must be no room for misunderstandings on this matter such as those which led to the breakdown of demobilization in 1918, and the same care must be taken in connexion with any and every class of specialist due for release in Class *B*. The efforts in regard to training for industry, whether for research or supervision and administration, and the work of Lord Hankey's Committee to which Mr. Bevin paid tribute, may all be frustrated unless this point is amply safeguarded. Every effort must be made to eliminate any suggestion of special pleading and to ensure that the release of teachers and students is in accord with the wise aims of the demobilization scheme and adequate to serve the country's needs, while avoiding any suggestion that professional interests are favoured other than as they first contribute to the national purpose.

## STATISTICAL THERMODYNAMICS

**Statistical Thermodynamics**

Course of Seminar Lectures delivered in January–March 1944 at the School of Theoretical Physics. By Erwin Schrödinger. (Hectographed.) Pp. ii+135. (Dublin: Dublin Institute for Advanced Studies, 1944.) 5*s*. net.

THIS little volume is not an ordinary text-book, dignified, dull and well printed (hence expensive), but an informal communication of ideas, fascinating, amusing and only hectographed (hence cheap). Its origin and background depend on the peculiar character of the Institute where these lectures were given.

The Dublin Institute for Advanced Studies, housed in one of the pleasant Georgian buildings forming Merrion Square, has at present only two departments, the School of Gaelic Language and the School of Theoretical Physics. The staff of the latter consists of the director, Erwin Schrödinger, and one professor, Walter Heitler, both known well enough in the world of mathematics and physics to need no introduction. The building contains a small but well-selected library, a lecture room and very com-

fortable rooms for the professors, students and guests. Lectures and seminars are given, not according to a fixed time-table and syllabus, but in response to the inclinations of the teachers and the demands of the students. All these attractions are crowned by the non-existence of examinations and degrees—an ideal place for scientific work.

My knowledge of these circumstances is due to the fact that I had the honour of taking part in one of the summer schools at the Institute (July 1943), together with Mrs. K. Lonsdale (Royal Institution, London) and P. P. Ewald (Belfast). These well-attended lectures and discussions on recent research on X-rays were conducted in the typical manner of the Institute—informal, but extremely informative for the students and the lecturers as well. No account of these courses has been published; but those of the previous year, given by Eddington and Dirac, have appeared in print.

The volume at present under review conveys an idea of the *ordinary* courses given at the Institute by its own staff. The programme is best explained in the words of the author himself: "Not a first introduction for newcomers to the subject is intended, rather a 'repetitorium'. The wording is extremely shortened about well known stories to be found in every one of a hundred textbooks, but more extended on some vital points, usually passed over in silence in all but large monographs (as Fowler's, Tolman's)".

The main feature is the systematic use of Gibbs' virtual assembly and the justification given for it. To quote again: "Here the $N$ identical systems are mental copies of the one system under consideration —of the one macroscopic device that is actually erected on our laboratory table. What on earth shall it mean physically to distribute a given amount of energy $E$ over these $N$ mental copies?". This question (given here verbatim to illustrate the style of the book) is answered thus: The $N$ identical systems loosely coupled are considered as a heat-bath of constant temperature and any one of them as the one actually existing. As experience shows that the nature of the heat-bath has no influence on the behaviour of a system in contact with it, this assumption is permissible, and it has great advantages with respect to simplicity and clarity of the argument: the number $N$ can be made arbitrarily large; in fact, one can always use the limit $N \rightarrow \infty$, so that there is no question about the applicability of Stirling's formula for the factorials of occupation numbers; and as each single system is macroscopic, no question about the individuality or indistinguishability of the members of the assembly can ever arise —as it does according to the 'new statistics' if single particles are considered as elements.

In this way the statistical considerations become very simple indeed; one has in all circumstances a Boltzmann distribution of macroscopic elements, but each of these elements is a system described by quantum laws, with a set of (discontinuous) energy states. Schrödinger gives a careful account of the two well-known ways of treating such an assembly, the method of the most probable distribution and the method of mean values due to Darwin and Fowler. The exact relation of these two methods is one of the weak points in most of the ordinary text-books, and a careful study of Section VI, p. 41, of Schrödinger's lectures is recommended to all who aim at a real understanding of physical statistics.

The first method is by far the simplest one, but can scarcely be considered as satisfactory in itself; Schrödinger proves it by demonstrating the identity of its result with that of the second method, which can be rigorously established. This result consists in the definition of the 'sum-over-states' or 'partition function' from which all thermodynamical properties can be derived by simple mathematical processes. The method of Darwin and Fowler for evaluating this sum as a residue (Cauchy's theorem) of a properly constructed generating function is called by Schrödinger a "sublimely excellent device"; and he adds: "But I beg you to keep those two things apart in your mind: *the general proof is done with.* When we use complex integration in what follows, it is *not* in the way of giving an example of the general method, only in the way of using a similar mathematical device or tool for evaluating certain sums-over-states. It is truly necessary to emphasize this point. For when a man has first explained a general method, then deals with particular examples and, in doing so, uses well-nigh the same mathematical device, you are almost bound to think that he does that, quâ applying the general method to the special example." I have quoted this sentence because it sets out a general rule for the teaching of science, which is violated in innumerable lectures and text-books.

The second half of the book contains applications to the $n$-particle system, mainly to the ideal gas. The 'new' statistics of Bose-Einstein and Fermi-Dirac appear as an immediate consequence of the way the total energy of a system of $n$ particles is assumed to depend on the energy levels of the single particles. Great stress is laid on "the failure of the classical theory" (p. 90) as expressed in Gibbs' paradox.

In the last section the theory of radiation is treated, first in the ordinary way leading to Planck's formula. The appearance of the infinite zero point energy then gives the cue for the introduction of a modification of this theory suggested recently by Peng and me. (It was in fact the first published account of it, based on letters, as our paper appeared some months later.) Whether these ideas have any future remains to be seen; I am rather sceptical, since Peng has meanwhile discovered that the difficulties of the ordinary field theories which were to be remedied by the new assumption (divergent integrals in the expressions for the interaction of different particles) are only due to bad mathematics and can be avoided without a new physical hypothesis.

Can scientific writing ever be called a work of art? There are doubtless many people who would claim this title for their own writing, as is illustrated by the true story of the young mathematician, let us call him Paul Lucky, who once went to Rome to attend an international mathematical congress. Not being interested in relics of the ancient world and the Renaissance, he spent all his time in lecture rooms, until his friends insisted that he ought to visit the Sixtine. There he stared awhile at the famous ceiling and said: "Not so bad. But if this chapel and all its paintings crumbled to dust, Paul Lucky's uniformization theorems will still stand."

Well, if there are other passports into the artists' elysium than durability, such as greatness of conception, harmony of structure, charm of expression, I do not know whether Paul has a chance of admission. But I think Schrödinger has; for he writes not only to instruct but also to please. I hope that many readers will enjoy this little work as much as I did. MAX BORN.

# THE CHEMICAL BOND, IN THEORY AND EXPERIMENT

## Valency: Classical and Modern

By Dr. W. G. Palmer. Pp. x+242. (Cambridge: At the University Press, 1944.) 10*s*. 6*d*. net.

THERE is no branch of chemistry in which greater progress has been made in the last twenty years than the study of valency. A full understanding of the principles of chemical combination demands a versatile mind: for it needs to be familiar with what we may call pure chemical reasoning and experiment; it must be on friendly terms with most, if not all, of the tools of modern physics (X-rays, electron scattering, vibration and rotation spectra, electric oscillations, and so on): and lastly, it must not despise mathematics (did not Dirac say, in effect, that all chemistry is a branch of mathematics ?). He who writes a book about valency must decide from the start what kind of approach he will make. To be all-inclusive would require more space than the bare 250 pages which Dr. Palmer has allowed himself; some selection has to be made.

"Valency: Classical and Modern" is a book about chemistry: it is written by a chemist for chemists. But it has this advantage over the old type of chemical treatise, that all other aids to understanding are welcome. So there are paragraphs about the measurement of dipole moments and the interpretation of spin and term diagrams, not usually found in such books. It is hard work fitting everything in, especially when the general approach is historical, so that space is also granted to Dalton and Berzelius. Indeed it is quite remarkable how much information is to be found in this little book. Thus we begin with a historical account of the ideas that led chemists to associate a definite valency (or several possible valencies) with a particular atom. This leads to the periodic system, though it is still unnecessary to introduce specifically electronic theories. The next chapter is devoted to various methods of determining structure and valency; these include stereochemistry studied optically, electric moments, electron diffraction and infra-red spectra. Having established our tools, we are prepared to accept the results that they give, group by group of the periodic table, in the following pages.

So far there is scarcely a mention of electrons; for example, bonds are polar because some unspecified charge is unsymmetrically distributed. But this is not sufficient; a theory of valency is needed, and in the next forty pages the electron spin theory is expounded. This involves us in descriptions of atomic *s* and *p* states and *s-p* hybridization. It is all rather condensed; but everything of importance at this level is included. No wonder that Dr. Palmer claims for these first chapters that "they present a compact but elementary account of classical and modern conceptions of valency . . . not overstraining the capacity of candidates for University examinations of the standard of Part 1 Natural Sciences Tripos at Cambridge". The claim is fair, though he would need to be a good candidate who really understood some of the quantum theory explanations.

There remain about a hundred pages. These are devoted to a series of special problems, with a distinctly more advanced flavour. It is good to see explained the failure of the octet rule for heavier elements: and even better to see so much space devoted to the method of molecular orbitals. Indeed, this is one of the very few chemistry text-books where the advantages of the molecular orbital theory are recognized. There is a lot to be said in favour of the theory if we want a simple visual clear-cut explanation of the multiple links of carbon, revealed, for example, in benzene and other aromatic substitutions. There is a final section on hydrogen bonds.

This latter part of the book is obviously more advanced than the first. It is a pity that it is marred be several mistakes. In one or two places the author appears confused in his description of allowed molecular orbitals. All this is probably explained by the present national circumstances, which make the very appearance of the book a matter for congratulation, but the mistakes (the reviewer has found more than half a dozen significant ones) ought to be corrected as soon as possible.

In conclusion, one cannot help comparing this book with Pauling's classical "Nature of the Chemical Bond". Dr. Palmer's historical approach first introduces the electron-pair bond on p. 112: Pauling introduces it in his first paragraph. The first method is valuable in showing how chemists have thought through their problems to their present knowledge, the second shows how they do think. Pauling has an axe to grind ('resonance, more resonance' is his meat and drink, as they will probably be his last words). But there will be many who will appreciate Palmer's book just because, having no such single idea, he can be fairer to all points of view. Yet this new book lacks the grand scale and manner which have rightly made Pauling's book so famous: "Valency: Classical and Modern" is a sound workmanlike book, but it is not a classic.

C. A. COULSON.

# ELECTRICITY IN PEACE AND WAR

## Electricity and its Application to Civilian and Military Life

By Charles A. Rinde. Pp. xii+467. (London: George Allen and Unwin, Ltd., 1944.) 25*s*. net.

THIS book is written round the United States War Department's outline, "Fundamentals of Electricity", and provides a broad foundation for the fields of specialization suggested by the various technical and field manuals. But its use is not confined to war-time applications of electricity. It is recognized that the same basic principles underlie civilian uses of electricity, and both civilian and military applications are stressed throughout.

The central theme unifying the book is the electron and the control of electrons, and quite rationally the electron is first introduced in the chapter on electrostatics, which comes quite early. It is excellent to find more than customary prominence given to the subject of X-rays, for, as the author very rightly says, "the X-ray is no longer merely a means of examining broken bones".

The text is simply written and easy to follow; it is thus very helpful to those students without previous knowledge of the subject. Many experiments are suggested for the student to carry out, and at the end of each chapter a useful set of questions and problems is provided. There is an abundance of illustrations, and the well-drawn and simple diagrams are a valuable asset to the book which, in spite of war-time conditions, is beautifully produced; a disadvantage is its rather high price.

# SCIENCE AND INDUSTRY IN NATIONAL SECURITY*

By THE HON. ROBERT P. PATTERSON
U.S. Under Secretary for War

THERE is a great voice in the world to-day, the voice of science and technology. It is a voice heard since ancient times but never until to-day has it spoken with such authority, have its words been so filled with promise, has it been listened to with such hope; and in no country in the world does the voice speak so eloquently as in the United States.

Science and technology have changed and are changing the lives of all men. Not a single aspect of our society but feels their advance. The things we make and use, the food we eat, the clothes we wear, the way we travel and communicate, the houses we build, the way we cure and prevent disease, the way we fight—and the way we shall win—have all been fashioned by science. Both war and peace move under the sign of research, discovery and invention.

While our thoughts and energies must still be devoted without stint or limit to the task of defeating Germany and Japan, second place in our thought and planning should be directed to the problems of the future. How shall we repair the ravages of war? How shall we create a society in which full production and full employment can be maintained? How shall we promote and maintain the security of the United States—and thereby contribute to the peace of the world—so that no aggressor will dare again to jeopardize our status as a free people. It is on the last question, on the part which science in industry can play by developing our resources, and advancing our technology in the interest of national security that I would speak.

I conceive the term national security to embrace a wider field than the maintenance of an adequate army, along with the development of powerful and effective weapons; because, in working on the normal products of peace, we at the same time make an essential contribution to our military strength. First, then let me briefly consider national security in its wider sense.

It is to the interest of all that America's scientific men engaged upon both pure and applied research should turn our swords into ploughshares as successfully as they have turned our ploughshares into swords. We shall need the development of new aeroplanes and helicopters, light metals and plastics, television and radio, new foods and medicines as much as we have needed and still need combat aircraft and jet propulsion, heavy armour and new explosives, radar and 'walkie-talkies', high-calorie rations, penicillin and blood plasma. I do not doubt that after victory we shall need the products of peace even more, for ours is not an aggressor country with imperialistic aims; the ideals of our nationalism are the ideals of peace and security.

To get the most out of all science, whether devoted to peace or war, there are certain things to be kept in mind. For one thing, research and development in industry, as in the university, flourish best in an atmosphere of complete freedom; control will wither science by destroying its precious essence of originality and spontaneity. If I were to add to the four freedoms of the Atlantic Charter, I might suggest a fifth—freedom of inquiry, experiment and research.

With that principle in the forefront of our thought, I think we must concede that in view of its position in the modern industrial State, in view of the way science is woven into the cloth of our society, it cannot be left unorganized and unsupported save by sporadic benefactions. A few of the great industries of the United States have been able to establish magnificent laboratories, and the discoveries and inventions flowing from them in a ceaseless stream have enriched our lives in peace and contributed heavily to our ultimate victory in this War. The laboratories of the universities of the United States, especially in the field of pure science, have steadily broadened and deepened the foundations on which all applied science must rest. The laboratories of the Federal Government, in the fields of agriculture, public health, medicine, meteorology and the development of the tools of war have also made an enviable record.

Essential as these contributions have been, we cannot afford to look exclusively to the laboratories and workshops of our major industries, universities and the Federal Government. While important scientific advances are not often made in attic, cellar or barn, as was the case not so long ago, we must not permit the precious stream of discovery flowing from smaller industry and smaller educational institutions to be dammed up by neglect. Small business needs technical information; universities not possessed of vast endowments need help; scientific research and development are of national interest, and whether they be devoted to national defence, public health, public housing or to normal scientific activity for commercial purposes, they must be encouraged, and if they need help they must have it.

Dr. J. B. Conant in a recent address said that the future of the physical sciences depends on the "number of really first class men" that can be turned out by our educational institutions. He urged that talented young men and women be afforded unhampered opportunity for research in both industrial and university laboratories; he advocated Federal scholarships for high-school graduates of technological promise, thus creating what he called "a scientific reserve" for national security. Without considering the exact means required to assure educational opportunities for young men and women of scientific promise, I am in full agreement with Dr. Conant's view as to the need and urgency.

Certain aspects of research, apart from the development of weapons, must, it seems to me, continue to receive Federal support or be carried on by the Federal Government. Agriculture, public health and housing fall in those categories. Certain economic problems also are in need of the clear light of science. The Federal Government, with unique access to full statistical data on population, manufacturing, crops, markets, methods of distribution, is in a position to help shed that light.

Nothing I have said should be construed to mean that in any of these fields the activities of the Federal Government should preclude or foreclose the research and development of private industry or the universities. In normal research and development during peace, the larger share must be contributed by the citizens and not by their Government. That is compatible with the view that in certain types of research the Federal Government must serve the needs of

* Address at the Silver Anniversary Forum on "The Future of Industrial Research", arranged by the Standard Oil Development Company, on October 5.

science. It must act as a stimulating force, it must furnish scientific information, it must lend financial support if it be needed.

In many scientific inquiries there is room for a co-ordination of effort. If it be deemed wise, the Federal Government might be called upon to participate in that function. There is urgent need for the fullest possible exchange of information between scientific workers in industry, academic centres and the Federal Government. How to achieve that co-ordination and a free exchange of data is a basic problem which has not been thought out to a satisfactory conclusion, although much work has been done upon it.

If I may sum up, the job of normal peace-time research is a private job, not a government job. Those branches in which the Government will continue in the principal role are well known; in no way do they conflict with the scientific functions of industry or university. What the Government may do, if it is called upon, is to furnish information and financial support. It may offer counsel, even leadership. It must not, in the normal researches of peace, assume control.

Up to this point I have been talking largely of scientific and technological research which, though of major importance in the national interest, will go on with or without any further plans we may make. But their advance will be facilitated if the factors to which I have briefly alluded are recognized and met.

Research and development devoted to the weapons, tools and techniques of war present us with a tougher problem. Such research will not go on to the extent required for our national security unless support, guidance, even control emanate from central mechanisms.

In time of war, when the nation's existence is in danger, no body of men responds more generously, with greater energy and zeal to the needs of their country than scientific men and technicians. That was our experience in the War of 1914–18; it is also our experience to-day. Industries and universities have turned their laboratories inside out to give their country what it needed, whether they were summoned or not. Men and women who people those laboratories have given us more than we dared hope for. Thousands of lives of our fighting men have been spared, most of the wounded restored to health. Our troops have been equipped with weapons equalling or surpassing those of the enemy; final victory has been brought immeasurably closer, as a result of the efforts of scientific men and technicians.

With all our grumbling, good-natured or otherwise, the fact is that on the home front in the United States we have scarcely felt the War, and that too is in large part to be ascribed to the efforts of our scientific workers.

But when peace comes, ours being a peace-minded nation, we shall have the greatest difficulty in keeping even a small portion of our best scientific brains on the job of maintaining the weapons of our Armed Forces at the high peak of effectiveness they now occupy; unless a suitable programme is evolved to draw and hold scientific men of the highest level, they will not be available for Government service in peace-time to supply the Armed Forces with the best science has to offer. They will return, as is only natural, to the industrial laboratories and the universities they came from. Nor will it be possible in the Government laboratories that will be continued in peace to carry through all the research in ordnance, aviation, radar, rockets and new weapons, in the many specialized nutritional, physiological and other fields which underlie the waging of modern total war. The research facilities and the scientific man-power prerequisite to these activities will simply not be available to the Government in sufficient degree. No acts of Congress or of the executive branch of our Federal Government can alone meet this deficiency. At almost every point of maintaining the technological strength of our Armed Services—whatever mechanism we devise to achieve this end—we shall have to turn to the research laboratories and the research workers of industry and the universities to fulfil our needs.

To some extent, as I mentioned at the outset, our task is made easier—paradoxically, I may say—because modern war is total war. In other words, much of the research carried on by industry and universities to meet the needs of peace will meet the needs of war if this tragedy should be thrust upon us again. In the field of chemicals, rubber, synthetic oil fuel, electrical instruments, engineering products, medicines, light and heavy metals, and food products, research for peace is research for national security. Also in the case of certain end products of purely military use, the intermediary products may be suitable for civilian consumption.

Research and development in connexion with most weapons are in a unique category. A host of factors stand as obstacles where the help of industry and the universities is concerned. Among these are the specialized tools and machinery required, the extensive proving grounds and test plants, the heavy expense, considerations of secrecy, the tenuous and inadequate liaison, during peace, between private industry and the Armed Services, the indifference or hostility of public opinion towards the development of war weapons in times of peace, the competing demands for commercial products.

Aware of the gravity of this problem and anxious to find at least a partial solution, some of the leading men of the National Academy of Sciences, the National Research Council, the Office of Scientific Research and Development and members of the Armed Services engaged upon research and development, have for some time past been weighing the merits of alternative plans for an organization which in the post-war world will deal with military scientific research and attempt to assure to the Armed Services the scientific help and interest required of industry and the universities. I would like to mention briefly some of the questions which this group has had before it, because I believe that these questions are in almost all respects similar to those which industry must answer in developing its policies for research and development pointed towards national security.

The first question is how shall we obtain for the Federal Government the full-time or consulting services of scientific men on the highest level.

It has been suggested that we need an agency, with distinguished leadership, such as we now have in the Office of Scientific Research and Development, and with ample funds, to promote precisely those branches of research and development which will effectively contribute to our military strength. For this is the type of research which if left unattended and unsupported cannot flourish. Between the War of 1914–18 and this War the funds made available for research and development in the military sphere were wholly inadequate. They are adequate now, but they must be kept so. The adequacy of Federal

appropriations to promote military research will determine, in large measure, the contribution that can be asked of private enterprise in terms of personnel and laboratory facilities. While the arguments for the creation of the new agency are impressive, I do not believe that such an agency would fully solve our problem. For the problem is essentially one of men and women, not of organizations. We must have sincere and spontaneous interest in research aiming at national security, and this does not grow out of organizations and subsidies alone, however important these may be.

An important obstacle in enlisting the aid of industry is the difficulty of liaison and interchange between the military services and industry. How can we best meet that problem, recognizing that there is one sphere fully and properly under military control, another fully and properly under private control, but there is a large area of both spheres common to both ? It is manifest that if industry's help in weapon development is needed, so far as the work requires, the military must take industry into their confidence, and vice versa. There must be an avenue between industry, university laboratories, government laboratories, and the Armed Services, and there must be no one-way signs upon it. How can we best achieve this end, not theoretically, but in day-to-day work ?

How shall extensive work in weapon development be financed ? To this there is no simple answer. No industry, however large, can be expected without government subsidy to undertake elaborate research for the weapons of war, especially the accelerated and ceaseless research peculiarly required in this field. How shall this subsidy be administered ? What is its probable magnitude over the next ten or twenty years ?

Financing by way of subsidy or contract payments will, I recognize, often not be enough. We shall need other forms of incentive, financial in character or otherwise. Over and above that, we shall need the approval, the sympathy, the leadership from civilian as well as military circles to enlist public opinion in support of a sound programme.

I know that the exchange of patents and licences in connexion with research on military products is many-sided and troublesome. I mention it also because of its particular concern to industry. I believe, however, that a solution for that question will not be difficult to find, once a basic framework for the entire research and development programme in the post-war world is erected.

What research facilities can and should the Government provide for industry and universities in the United States ? We cannot expect that the research facilities of the Federal Government will be increased after the War ends. We cannot expect, on the other hand, that even the largest industries will be able to provide the proving grounds and more especially the test plants, so that we can convert the successful solution of laboratory problems to successful solutions in production. Proving grounds will doubtless be made available to industry. What of pilot plants ? These questions are, of course, intimately related with the problem as to what research functions in the development of weapons the Federal Government itself ought to continue to perform.

Planning for the results of science is unwise, for results cannot be anticipated. But we must not forgo plans for research, suggestions in definite fields in which valuable results may reasonably be anticipated.

My friends who are scientific workers tell me that so rich and limitless, so untapped are the possibilities of science that the discipline of planning consists as much in saying what roads ought *not* to be followed as what roads ought to be. At every stage of developing our research on weapons we must have a standard of values, so that although research would not be confined, lesser problems would be subordinated to questions of vital national need. That standard of values must be keyed to the current strategic thoughts of our military leaders and must be accessible to the leaders of research. If the link fails in either respect, we cannot expect to gain the full benefit of our vast research machinery. Repeatedly this War has shown that science leads tactics ; this will be fully as true in wars of the future. We will make our plans to suit our weapons, rather than our weapons to suit our plans.

The U.S. War Department has grown increasingly aware of the need for research and development in connexion with new weapons. In partial response to that need there was created within the War Department, more than a year ago, the New Developments Division. This Division is charged with functions relating to the initiation and co-ordination of research and development and the expeditious application of new weapons, devices and techniques. It has proved its usefulness, and will, I hope, continue to do so in increasing measure. Its working relationship with the two scientific agencies to which we all owe so much, the National Research Council and the Office of Scientific Research and Development, has at all times been close and effective. I realize that this Division marks only the beginning of the road to our goal. For in every one of its activities, after the War as now, the War Department must train its men, shape its plans and its actions so as to reflect the most recent advances of science. It must not lose sight of the fact that significant discoveries and inventions are usually the matured products of years of thought and experiment, with innumerable disappointments and failures along the way.

In my judgment a single unified defence agency combining the Army and Navy would go far towards solving many of the problems to which I have referred. The establishment of a corps of scientifically trained officers, for which persuasive arguments have been offered, is only one step of many which the creation of a unified defence agency would facilitate. It is a step which merits serious attention, whether or not a peace-time scientific agency, of the kind I mentioned before, is created. It envisages the training of a group of talented young scientific men, and others with professional skills, within the existing framework of the Armed Services, as an integral part of the U.S. Army and Navy. Members of this group would have their regular basic military training at the academies. Once their talents were demonstrated, they would be given full opportunity to keep pace with the advance of science by postgraduate work in universities and industry. They would be assigned to the research and development branches of the several services in accordance with proved ability. They would grow within the services, be acquainted with their problems and contribute not only in terms of professional skill, not only in propagating the views of science, but also in linking the scientific and technical activities in universities and industry with the parallel activities of the Armed Services. This is a concept that commends itself to our attention ; it is one on which the U.S. War

Department is most anxious to hear the views and criticisms of industry.

I cannot leave these points without mentioning again the matter of science in education which I referred to before. The future does not belong to us. It belongs to our children and to their children. We must look to them for the future of science. Unless we give them the training, the opportunities, the facilities for turning their talents and their genius into a powerful and disciplined machine, we cannot envisage a bright future for science in America.

It is a heavy assignment of responsibility to say that the future of the United States in peace and in war is to a great extent in the hands of American men of science in industry, in schools, in universities and in government. But I believe the responsibility is properly assigned, and I have confidence it will be met. Vice-President Wallace once stated that science and technology, like good will, have no natural boundaries. The opportunities, the freedom, the security which science can give to our people can be extended to the corners of the earth. By so extending them industry will make its greatest contribution to national security. The perils of war give the precepts of peace. With the help of science and the men and women who make it we shall maintain that peace.

# NATIONAL FLOUR (82½ PER CENT EXTRACTION) AND BREAD

### Sixth Report from the Scientific Adviser's Division, Ministry of Food

ON October 1 last the extraction of National flour in Great Britain was reduced to 82½ per cent. This lowering of the extraction followed work which showed that the bulk of the vitamins and minerals in the wheat grain are located in the germ, particularly the scutellum fraction, and in the outer endosperm adjoining the bran. Provided these two fractions are included in the flour, there will be no appreciable difference in the nutritive value of 82½ per cent as compared with 85 per cent extraction flour. At the same time, the fall in the extraction makes it possible to exclude about 1·6 per cent of bran (on the average, 85 per cent flour contains 4 per cent bran) and so give a whiter flour and bread. Details of the milling technique necessary to produce a satisfactory 82½ per cent flour have been circulated to all millers[1].

## Quality of Flour

Mills were allowed about a fortnight to settle down, after which each mill was instructed to send a 6-lb. sample once a week to the Cereals Research Station, St. Albans, for analyses. These covered colour, fibre, ash, added calcium, iron, vitamin $B_1$, riboflavin and nicotinic acid; in addition, the flours were examined for baking quality.

It was impossible to examine every sample in every respect each week. Thus, the 'colour' of every sample was judged each week; vitamin $B_1$ was determined on samples from all the larger mills every week, and on the remainder once in four weeks, thus covering more than 80 per cent of the total national flour production—on a capacity basis—every week; calcium (as added creta præparata) was determined fortnightly on all samples; fibre and ash were determined on all samples sent by Ministry of Food inspectors, while the remainder of the mills were covered in about eight weeks; about forty flours were baked every week, thus covering all the mills in six or seven weeks. All mills included in the survey were grouped according to their capacity (five groups: up to 5, 6–10, 11–20, 21–50, and more than 50 sacks/hr.) and their port area (London, Bristol, Liverpool, Hull, Leith, Glasgow, and Northern Ireland). Aliquots of samples from all mills in the same capacity-group in each port area were bulked together to form a total of thirty compound samples upon which riboflavin, nicotinic acid and iron were determined fortnightly.

The production of a whitish flour of high nutritive value is a new development, and so the analytical results are given in some detail.

*Colour Index.* Colour (bran speck contamination) was judged on a scale of 0 to 100, where 0 represented a white flour free from visible bran specks, and 100 represented the national average 85 per cent flour (capacity basis) as manufactured during July–September, 1944.

The percentage of all samples examined that fell within the various colour index classes week by week is shown below. The average colour indexes on a mill basis and on a capacity basis are also shown.

| Colour Index not exceeding | Week commencing | *A* Oct. 16 | *B* 23 | *C* 30 | *D* Nov. 6 | *E* 13 | *F* 20 | *G* 27 |
|---|---|---|---|---|---|---|---|---|
| 10 | | 3 | 5 | 4 | 5 | 3 | 2 | 2 |
| 20 | | 5 | 8 | 12 | 19 | 15 | 11 | 15 |
| 30 | | 15 | 21 | 29 | 36 | 29 | 30 | 30 |
| 40 | | 27 | 34 | 42 | 49 | 50 | 48 | 50 |
| 50 | | 46 | 49 | 54 | 66 | 54 | 61 | 62 |
| 60 | | 59 | 65 | 69 | 75 | 68 | 77 | 79 |
| 70 | | 76 | 80 | 79 | 87 | 80 | 85 | 89 |
| 80 | | 85 | 87 | 88 | 91 | 92 | 91 | 94 |
| 90 | | 89 | 92 | 92 | 92 | 93 | 94 | 96 |
| 100 | | 91 | 94 | 94 | 96 | 96 | 97 | 98 |
| Average Colour Index | Mill basis | 59 | 55 | 53 | 47 | 49 | 49 | 47 |
| | Capacity basis | 51 | 45 | 43 | 36 | 38 | 38 | 37 |
| No. of samples | | 226 | 226 | 237 | 246 | 248 | 247 | 254 |

*Vitamin $B_1$.* The percentage distribution of vitamin $B_1$ values and the weekly average vitamin $B_1$ value (mill basis) were as follows:

| $B_1$ (I.U./gm.) | Week commencing | *A* Oct. 16 | *B* 23 | *C* 30 | *D* Nov. 6 | *E* 13 | *F* 20 | *G* 27 |
|---|---|---|---|---|---|---|---|---|
| 1·10 or more | | 2 | 0 | 0 | 0 | 0 | 1 | 0 |
| 1·05 ,, ,, | | 6 | 0 | 0 | 0 | 1 | 2 | 0 |
| 1·00 ,, ,, | | 18 | 3 | 4 | 4 | 4 | 4 | 3 |
| 0·95 ,, ,, | | 38 | 17 | 20 | 11 | 20 | 13 | 11 |
| 0·90 ,, ,, | | 59 | 38 | 43 | 38 | 45 | 38 | 35 |
| 0·85 ,, ,, | | 79 | 65 | 62 | 58 | 68 | 65 | 53 |
| 0·80 ,, ,, | | 91 | 88 | 78 | 84 | 89 | 85 | 78 |
| 0·75 ,, ,, | | 97 | 96 | 90 | 94 | 97 | 95 | 86 |
| 0·70 ,, ,, | | 99 | 97 | 97 | 98 | 99 | 97 | 93 |
| 0·65 ,, ,, | | 100 | 98 | 99 | 100 | 99 | 98 | 96 |
| 0·60 ,, ,, | | | 98 | 99 | | 100 | 99 | 98 |
| 0·55 ,, ,, | | | 100 | 100 | | | 100 | 99 |
| No. of samples | | 99 | 118 | 112 | 117 | 112 | 119 | 130 |
| Mean vitamin $B_1$ value | | 0·92 | 0·87 | 0·87 | 0·86 | 0·88 | 0·87 | 0·85 |
| Per cent of the total milling capacity analysed | | 82 | 84 | 81 | 83 | 81 | 81 | 83 |

The average value for vitamin $B_1$ over weeks *A* to *D* (during which all mills were covered), on a capacity basis, was 0·88 I.U./gm.

*Riboflavin, nicotinic acid and iron.* The average values for these constituents (mill basis) are given in the following table:

| | Fortnight commencing Oct. 16 | Oct. 30 | Nov. 13 | Average for six weeks |
|---|---|---|---|---|
| Riboflavin ($\mu$gm./gm.) | 1·0 | 1·0 | 1·0 | 1·0 |
| Nicotinic acid ($\mu$gm./gm.) | 18 | 18 | 19 | 18 |
| Iron (mgm./100 gm.) | 1·99 | 1·99 | 1·84 | 1·94 |

*Ash and fibre.* The average ash and fibre determinations (mill basis) on samples sent by mill inspectors were as follows:

| Week commencing | *A* Oct. 16 | *B* 23 | *C* 30 | *D* Nov. 6 | *E* and *F* 13 and 20 | *G* Nov. 27 | All samples *A* to *G* |
|---|---|---|---|---|---|---|---|
| Av. ash (per cent) | 0·92 | 0·87 | 0·93 | 0·85 | 0·90 | 0·82 | 0·88* |
| Av. fibre (per cent) | 0·27 | 0·29 | 0·28 | 0·32 | 0·27 | 0·30 | 0·29 |
| Av. fibre (per cent) (corrected for added white flour) | 0·29 | 0·31 | 0·30 | 0·35 | 0·30 | 0·33 | 0·31 |
| No. of samples | 14 | 8 | 11 | 5 | 7 | 11 | 56 |

* Includes 0·12% due to added creta.

*Creta Præparata.* The average value found for the amount of added creta præparata over the last complete month (commencing October 30) was 6·5 oz./sack. The distribution of the figures was as follows:

| Creta (oz./sack) | % of all samples |
|---|---|
| 10 or more | 4·5 |
| 9 ,, ,, | 10·2 |
| 8 ,, ,, | 18·6 |
| 7 ,, ,, | 36·5 |
| 6 ,, ,, | 61·3 |
| 5 ,, ,, | 79·4 |
| 4 ,, ,, | 90·6 |
| 3 ,, ,, | 94·7 |
| 2 ,, ,, | 96·5 |
| 1 ,, ,, | 98·5 |

Hence, 60·8 per cent of all the samples had a value lying between 5·0 and 7·9 oz./sack. This table summarizes the results of analyses on 491 samples of flour.

*Breadmaking quality.* A number of flours were taken at random each week, the object being to cover all mills in due course. These flours were baked in the laboratories under ideal conditions, and the resulting loaves judged for volume, colour and quality of the crumb. The numbers of loaves described as good, fair-good, fair and poor were as follows:

| Quality of loaves | Weeks commencing Oct. 16 | Oct. 23 | Oct. 30 | Nov. 6 | Nov. 13 | Nov. 20 | Nov. 27 | Total for 7 weeks No. of loaves | % of total |
|---|---|---|---|---|---|---|---|---|---|
| Good | 18 | 25 | 29 | 16 | 26 | 31 | 8 | 153 | 62 |
| Fair-good | 12 | 5 | 8 | 4 | 5 | 4 | 2 | 40 | 16 |
| Fair | 8 | 2 | 6 | 3 | 7 | 6 | 3 | 35 | 14 |
| Poor | 7 | 2 | 3 | 1 | 4 | 2 | 1 | 20 | 8 |

Out of the 248 samples of flour examined, 60 (= 24 per cent) showed signs of high maltose due to the inclusion in the grist of sprouted English wheat.

With the fall in extraction from 85 to 82½ per cent, the water absorption of the flour has decreased by ½ gallon per sack. Actually, as shown later, the percentage of Manitoba wheat in the grist has increased from about 40 per cent in the first six months of 1944 to about 57 per cent in October and November. Had the percentage of Manitoba remained at 40 per cent, the water absorption would have decreased by about 1 gallon per sack.

The conversion factor of 82½ per cent flour to bread is approximately 1·33.

*Colour of bread crumb and colour index of flour.* There was a reasonably good relation between colour of bread and colour index of flour as shown in the following table:

| Colour of bread crumb | Mean Colour Index of flours used for baking Oct. 16 | Oct. 23 | Oct. 30 | Nov. 6 | Nov. 13 | Nov. 20 | Nov. 27 | Average for seven weeks | |
|---|---|---|---|---|---|---|---|---|---|
| Very pale | 34 | 41 | 31 | 35 | 36 | 35 | 32 | 35 | (43)* |
| Pale | 57 | 52 | 53 | 37 | 49 | 49 | 64 | 52 | (33) |
| Fairly pale | 97 | 80 | 63 | 65 | 55 | 72 | 73 | 71 | (18) |
| Brownish† | | | 95 | | 95 | 90 | | 92 | (4) |
| Dark brown | | | | | 100+ | 100+ | | 100+ | |

* Figures in brackets are percentages of total number of loaves examined.

† 'Brownish' corresponds to loaf made from average 85 per cent extraction flour.

## Correlation Between Flour Colour and Fibre, and Between Flour Colour and Vitamin $B_1$ Content

*Flour colour and fibre.* All samples analysed for fibre were arranged in groups according to the colour index, and the average fibre content for each group was calculated. There is a close relationship between colour index and fibre content, indicating that the colour index can be used to give a fair estimate of the fibre content.

*Flour colour and vitamin $B_1$ content.* All samples analysed for vitamin $B_1$ during the last complete month (commencing October 30) were similarly arranged in colour-index groups, and the average vitamin $B_1$ content of each group was calculated. Since samples from the large mills (more than 20 sacks/hr.) were analysed each week, the monthly averages for vitamin $B_1$ and colour index were calculated for each mill and these values were used instead of individual determinations. The complete lack of correlation between colour and vitamin $B_1$ indicates that, in general, millers who are getting good colour in their flour are *not* doing so to the detriment of its $B_1$ content. This is to be expected since bran, as such, contributes little to the vitamin $B_1$ content of flour.

| Colour Index | Average fibre content (per cent) | Average vitamin $B_1$ content (I.U./gm.) |
|---|---|---|
| 10 | 0·23 (25)* | 0·88 ( 9)* |
| 20 | 0·24 (15) | 0·86 (29) |
| 30 | 0·24 (19) | 0·87 (47) |
| 40 | 0·27 (14) | 0·86 (41) |
| 50 | 0·28 (20) | 0·88 (34) |
| 60 | 0·31 (26) | 0·86 (35) |
| 70 | 0·33 (27) | 0·85 (29) |
| 80 | 0·34 (28) | 0·88 (16) |
| 90 | 0·36 ( 8) | 0·89 ( 7) |
| 100 | 0·38 (13) | 0·89 ( 5) |
| 100+ | 0·48 (34) | 0·89 ( 9) |

* The number of determinations is shown in parentheses.

## Comparison of 82½ Per Cent Flour with 85 Per Cent Flour

Average figures for 82½ per cent extraction flour as given above are set against figures for 85 per cent flour as given in the 5th Report[2] (covering 85 per cent flour samples received during January–June, 1944).

| | | 82½% flour | | 85% flour | |
|---|---|---|---|---|---|
| Vitamin $B_1$ (I.U./gm.) | (Sample basis) | 0·88 | (807)* | 0·975 | (346)* |
| Riboflavin (μgm./gm.) | ,, | 1·0 | (723) | 1·3 | (346) |
| Nicotinic acid (μgm./gm.) | ,, | 18 | (723) | 17 | (346) |
| Iron (mgm./100 gm.) | ,, | 1·94 | (723) | 2·07 | (346) |
| Protein (per cent) | ,, | 11·6 | (245) | 10·7 | (346) |
| Fibre (per cent) | ,, | 0·31 | ( 56) | 0·50 | (346) |
| Ash (per cent) | ,, | 0·88 | ( 56) | 0·98 | (346) |
| Colour Index | ,, | 51 | (1684) | — | — |
| Colour Index | (capacity basis) | 41 | (1684) | 100 | (200) |

* The values represent averages for the number of samples given in parentheses.

In the report on High Vitamin Flour[1] it was predicted that the lowering of extraction by 2½ per cent would entail a reduction of the bran content of the flour from 4 per cent to 2·4 per cent, and that the 82½ per cent flour would have an average fibre content not exceeding 0·3 per cent. This prediction has been justified in the average figure of 0·29 per cent of fibre (0·31 per cent when corrected for added white flour). This lowering of fibre content is reflected in the lighter colour of the flour. The ash content has also decreased slightly. The vitamin $B_1$ content has dropped rather more than the theoretical prediction of 0·02 I.U./gm., and this, taken in conjunction with the drop in riboflavin content, suggests that some scutellum and embryo are being lost to the offals.

The iron content has shown roughly the forecast decrease of 0·16 mgm./100 gm. On the other hand, the nicotinic acid content, instead of decreasing, has actually increased slightly. The explanation of this anomaly is probably to be found in the composition of the grists used in milling the 85 per cent flour analysed during the first six months of 1944 and those being used for the 82½ per cent flour in October and November. The following table gives details of the grists.

| | Average composition of grist in samples analysed | | | |
|---|---|---|---|---|
| | Manitoba wheat | Home-grown wheat | Other wheat | Barley and rye |
| 85 per cent extraction survey: | | | | |
| January | 37·4 | 59·5 | 0·5 | 2·6 |
| February | 39·7 | 57·3 | 0·5 | 2·5 |
| March | 35·3 | 61·1 | 2·1 | 1·5 |
| April | 38·3 | 58·4 | 2·8 | 0·5 |
| May | 42·7 | 53·2 | 3·6 | 0·5 |
| June | 42·6 | 54·2 | 3·0 | 0·2 |
| 82½ per cent extraction survey: | | | | |
| October 16–30 | 57·0 | 38·1 | 3·8 | 1·1 |
| October 30–November 13 | 57·1 | 38·1 | 3·8 | 1·0 |
| November 13–27 | 57·7 | 37·7 | 3·7 | 0·9 |

The higher Manitoba content of the grist used in making 82½ per cent flour is reflected in the higher protein content of this flour compared with 85 per cent flour.

Further, Manitoba wheat is richer in nicotinic acid than English wheat. An average figure for Manitoba wheat is 60μgm./gm. against 45μgm./gm. for English wheat.

The amount of added white flour during 1944 has varied between 5 and 12½ per cent. The bulk of this flour is Canadian G.R. (fortified with vitamin $B_1$ to a level of approximately 1 I.U./gm.), but small quantities of Plate and, just recently, American fortified flour have also been added. Average figures for this last flour are vitamin $B_1$ 1·5 I.U./gm.; riboflavin 2·7 μgm./gm.; nicotinic acid 36 μgm./gm.; and iron 2·9 mgm./100 gm. It is understood that during the period when the 82½ per cent flour samples were analysed, the overall addition of American enriched flour was well below 2 per cent. Even at 2 per cent level, however, the American flour would only increase the values for 82½ per cent flour by the following amounts: vitamin $B_1$, 0·01 I.U./gm.; riboflavin, 0·03 μgm./gm.; nicotinic acid, 0·4 μgm./gm.; and iron, 0·02 mgm./100 gm. Plate flour and Canadian G.R. flour (except as regards vitamin $B_1$, where it has no effect) would act in the opposite direction.

### Quality of Bread

971 commercial loaves from different parts of Great Britain have been examined during the period October 1–November 30. These were graded for quality (commercial standards) with the following results:

| | | | | | |
|---|---|---|---|---|---|
| Good | = | 98 loaves | = | 10·1 | per cent |
| Fair–Good | = | 427 ,, | = | 44·0 | ,, ,, |
| Fair | = | 266 ,, | = | 27·4 | ,, ,, |
| Poor | = | 180 ,, | = | 18·5 | ,, ,, |

Unfortunately, this harvest was a particularly wet one, and much British home-grown wheat sprouted in the stack. Such wheat has a high maltose content and tends to give a loaf with a doughy crumb. The results, described earlier in this report, showed that some 24 per cent of the flours received from mills gave loaves showing high maltose damage. Of the commercial loaves 298 (= 31 per cent) showed the same defect, and as a result the total percentage of 'Good' and 'Fair–Good' loaves (54 per cent in all) was lower than would otherwise have been the case. There was, however, a marked improvement in the colour of the loaves compared with those made from 85 per cent flour.

This work was carried out at the Cereals Research Station, Ministry of Food, St. Albans.

## OBITUARIES

### Prof. C. G. Barkla, F.R.S.

CHARLES GLOVER BARKLA, Nobel Prizeman in Physics for the year 1917, died at his home, Braidwood, Edinburgh, on October 23. The news came as a shock to his friends, for his death occurred rather suddenly. He had been in poor health for some months and had undergone an operation in June. He had, however, recovered from that and was back at work, looking well and seemingly his bright, happy self again, when suddenly he collapsed, was ill for a week and died.

Barkla was the son of John Martin Barkla, a former secretary of the Atlas Chemical Company of Widnes, in which town Charles was born on June 7, 1877. He was educated at the Liverpool Institute, from which he proceeded to University College, Liverpool, where he read for an honours degree in physics. He graduated in 1898 and obtained the master's degree in the following year. In 1899, on the nomination of his College, he was awarded a research scholarship by the Royal Commissioners for the Exhibition of 1851, and went to Cambridge in the autumn of that year, being admitted to Trinity College as an 'advanced student'. He began research work at the Cavendish Laboratory by investigating the velocity of electric waves along wires of various materials and of different thickness. He studied also the absorption of electric waves by dielectrics. The scholarship was in the first instance for two years, but Barkla's tenure was exceptionally renewed for a third year. It was during this additional year that he commenced his investigations of secondary X-radiation, and so entered the field of research work with which his name will always be associated.

After one year at Trinity, Barkla migrated to King's College. He possessed a powerful baritone voice and during his first year at Cambridge had contemplated the delight of singing in the choir of a chapel of the size and magnificence of King's. Dr. Mann, the organist of King's, encouraged the migration, and Barkla became a member of King's College choir and a regular attendant both at practices and services. His magnificent singing added to the reputation of the College chapel in that respect, and, in his last year at Cambridge, if it became known that Mr. Barkla was to sing the solo part in an anthem, the great chapel of King's was crowded for the occasion.

On leaving Cambridge in 1902, Barkla was elected to the Oliver Lodge fellowship of the University of Liverpool, which he held for three years, continuing his researches on X-rays. During the period 1905–9 he was successively demonstrator, assistant lecturer in physics and special lecturer in advanced electricity at the University. He was then appointed to the Wheatstone chair of physics in the University of London (King's College) in succession to H. A. Wilson, who was leaving to succeed Rutherford at Montreal.

The Royal Society elected Barkla to its fellowship in 1912, and in the following year he accepted the professorship of natural philosophy in the University of Edinburgh, which he held until his death.

During the most active period of his life, Barkla's investigations dealt mainly with X-rays and their absorption by matter, and with the emission of secondary radiation. He was the first to show that the secondary emission is of two kinds, one consisting of X-rays scattered unchanged in quality, and the other a 'fluorescent radiation', characteristic of the scattering substance and accompanied by selective absorption of the primary beam. The secondary radiation of the first kind Barkla showed to be polarized, an experimental result of fundamental importance, for it indicated that X-radiation was to be regarded as similar to ordinary light, a point which, up to that time, was thought to be doubtful.

For the discovery of the characteristic radiation and for the explanation of its origin Barkla was most deservedly awarded the Nobel Prize for Physics in the year 1917. His outstanding achievements were also recognized by the Royal Society, which appointed him Bakerian Lecturer for 1916 and awarded him the Hughes Medal in the following year.

Barkla was a successful teacher who inspired many of his pupils with an enthusiasm for research. He was in great request as an examiner in physics, and few excelled him at this work. His long experience of students in three universities, the wide range of his knowledge of physics, his judgment and common sense made him an eminently fair and discriminating examiner. He would re-read with extreme patience (not always shared by his co-examiner) any script of a 'border-line' candidate which he found difficult to assess, and his verdict, when finally delivered, could be accepted with confidence.

While a lecturer at Liverpool, Barkla married Mary Esther, eldest daughter of the late John T. Cowell, receiver-general of the Isle of Man. He leaves two sons and a daughter. Only in the last year was his life clouded by indifferent health; but the family had previously suffered a grievous loss by the death at Carthage in August 1943 of the youngest son, Flight-Lieutenant Michael Barkla, whose achievements at school and at the university had given promise of a career no less brilliant than that of his distinguished father.

Those who were privileged to know Barkla well will treasure the memory of his open-hearted friendliness and personal charm, of the delights of the Hermitage of Braid—his earlier home in Edinburgh—and of the almost idyllic happiness of his domestic life there.

FRANK HORTON.

## Prof. G. D. Birkhoff

THE many friends of Prof. G. D. Birkhoff on the eastern side of the Atlantic are deeply grieved to hear of his death on November 12. For a whole generation he had been a commanding figure among mathematicians and a link between American men of science and their colleagues in both western and eastern Europe.

George David Birkhoff was born at Overisel, Michigan, on March 21, 1884; as the name would indicate, his family was originally Dutch, but it has long been settled in the United States. He studied first at Chicago and then at Harvard, returning to Chicago for his doctorate; and, after a short period as instructor in the University of Wisconsin, was appointed assistant professor of mathematics at Princeton in 1909. It was here that he wrote the memoir on the "General Theory of Linear Difference Equations" (*Trans. Amer. Math. Soc.*, 1911) which first brought him into prominence; the "Jahrbuch über die Fortschritte der Mathematik" devoted more than two pages to a notice of it, a rare honour for a young and unknown author. Fundamental solutions of linear difference equations with rational coefficients were obtained for the entire plane of the complex variable by direct matrix methods, and their nature was studied from the functional point of view. Birkhoff showed that there exists a purely Riemannian theory of the equations, and found quantities which play a part like that of the monodromic group constants of an ordinary linear differential equation. His methods were of wide generality, and the paper constituted a striking advance in the subject, to which he made further contributions from time to time, notably in a memoir in *Acta Math.*, 54 (1930).

A closely related branch of mathematics which also owes much to Birkhoff is the theory of linear differential equations, on which he published many memoirs from 1910 onwards (*Proc. Amer. Acad.* and *Trans. Amer. Math. Soc.*); the earlier ones were particularly concerned with the problem of constructing systems of linear differential equations with prescribed singular points of given character and with a given monodromic group.

Birkhoff's interests were shared between pure and applied mathematics, and his work in dynamics was of great value. In an extensive memoir—almost a complete treatise—on "Dynamical Systems with Two Degrees of Freedom" (*Trans. Amer. Math. Soc.*, **18**; 1917), he reduced all problems relating to such systems, even in the 'irreversible' case, to the problem of determining the orbits of a particle constrained to move on a smooth surface which rotates about a fixed axis with uniform angular velocity and which carries with it a conservative field of force; and he showed how the existence of periodic solutions may be directly inferred, and their form determined. This investigation was followed by others, especially on periodic orbits and the problem of three bodies (*Acta Math.*, *Amer. J. Math.* and elsewhere); a connected account of much of his dynamical work appeared in 1927 as one of the American Mathematical Society's Colloquium volumes, under the title "Dynamical Systems".

His two books on relativity, "Relativity and Modern Physics" (1923) and "The Origin, Nature, and Influence of Relativity" (1925) were useful and widely read, and characteristically original in treatment.

In later life, Birkhoff became much occupied with the discovery of mathematical relations in æsthetics. As is well known, more than two thousand years ago Pythagoras founded the scientific theory of music by showing that simple numerical ratios exist between the lengths of the strings the notes of which yield agreeable melodic progressions. Birkhoff's aim was to create a theory of similar character for the fine arts: the results obtained were described in his book "Aesthetic Measure", published in 1933.

Birkhoff was professor of mathematics in Harvard University from 1919 onwards, president of the American Mathematical Society during 1924–26, president of the American Association for the Advancement of Science during 1936–37; an honorary doctor of many American universities and of St. Andrews, Poitiers, Paris, Athens and Sofia;

a foreign member of many European academies (including the Institut de France, the Lincei and the Pontifical Academy) and mathematical societies, and an Officier de la Legion d'honneur. His last years were gladdened by the knowledge that his brilliant son Garrett was steadily advancing towards a position in the world of mathematics not inferior to his own.

E. T. WHITTAKER.

## Dr. O. F. Bloch

OLAF BLOCH was a man of remarkable energy largely applied to the progress of photographic science and in furthering the application of photography as a tool in many branches of science and technology. He received his earliest scientific training at the Finsbury Technical Institute under Prof. H. E. Armstrong, and having spent some years in the Davy Faraday Laboratory and in chemical manufacture, he joined the staff of Ilford, Ltd., in 1910. Little can be written of his very successful work over many years to produce improved light-sensitive materials, for much of it was made known only to his closest associates and publication in this field is rare; but mention may be made of important work with F. F. Renwick on the optical properties of photographic layers, and early attempts, with Miss F. M. Hamer, to relate the chemical structure of cyanine dyes with their sensitizing properties.

As secretary of the Scientific and Technical Group of the Royal Photographic Society in the years following the War of 1914–18, Bloch took a leading part in organizing an attack on the problem of the sensitometric testing of photographic materials, leading to recommendations to the Sixth International Congress of Photography in Paris in 1925.

Bloch became chief chemist of Ilford, Ltd., in 1930, and his devoted work for the Royal Photographic Society was recognized by his election to the presidency in the following year. His ready wit and wide knowledge made him a most popular lecturer, and he addressed many of the learned societies in Great Britain. He will be particularly remembered for his accounts of the many applications of infra-red photography, just then made really practicable by the discovery and application of thiatricarbocyanines. Later he turned to demonstrating the importance of photography as an indispensable tool in many branches of science and industry, and in these lectures Bloch referred always to his conviction that photography is grossly neglected by British universities as a subject for teaching and research. The foundation of a chair of photographic science at a university in Britain was a cause very dear to him, so that he found particular pleasure in helping academic scientific workers in their photographic problems. Thus by collaboration with Dr. F. W. Aston he produced plates especially designed for recording atomic particles of low penetration, and these were used in the classical investigation of isotopes. A range of materials of special characteristics and spectral sensitivities was prepared for use in astronomy and related sciences. More recently, Bloch eagerly accepted opportunities to collaborate with atomic physicists to evolve photographic emulsion layers of value in recording tracks produced by penetrating atomic particles.

These and other services to scientific investigation were recognized by the University of Aberdeen by the award of the honorary degree of LL.D. He received the Progress Medal of the Royal Photographic Society, and, appropriately, was chosen to preside at the commemoration of the centenary of photography at the Royal Society of Arts in 1939.

Away from his work, Bloch had a remarkable range of interests; he was deeply appreciative of literature and the arts, and was a keen gardener with an encyclopædic knowledge of garden plants. Taking up alpine mountaineering with characteristic enthusiasm when more than fifty years old, he qualified for membership of the Alpine Club. He died on October 19 at the age of seventy-two years.

C. WALLER.

WE regret to announce the following deaths:

Sir John Fox, C.B., O.B.E., F.R.S., Government chemist, on November 28, aged seventy.

Sir Percy Nunn, first director of the Institute of Education, University of London, on December 12, aged seventy-four.

# NEWS and VIEWS

## Ethics of Scientific Investigation

IN his address "Human Nature in Science" to the Section on Geology and Geography of the American Association for the Advancement of Science, delivered at Cleveland on September 13, 1944 (*Science*, **100**, 299; 1944), Dr. J. K. Wright gave a highly stimulating discussion of some relations between human nature and science as they might be set forth in such a manual for science as Macchiavelli wrote for princes. Analysing first the personal qualities that influence scientific research, especially originality, open-mindedness, precision and scientific consciousness or the ability to discriminate between motives, Dr. Wright indicates the dangers which may attend excess of any one of these qualities. He surveyed next the motives for scientific research; these are first classified as pro-scientific, anti-scientific or non-scientific, according to whether they promote, retard or have no effect on the advancement of science; and again as personal, group or disinterested motives, depending on whether they spring from a desire to serve individual, group or no particular interests. In this analysis, Dr. Wright has wise and stimulating words about opinions or judgments of the relative worth of scientific investigations. Qualitative judgments are fairer than formal judgments, for they take account of the degree of good sense, originality, accuracy and open-mindedness to which the study bears witness, as well as of the suitability of the form and substance to the solution of the problem in hand. The preliminary work required before scientific laws can be formulated may be quite as scientific as the subsequent processes of interpretation to which it leads; and an economic law may be fully as scientific as the law of eclipses, provided all available evidence is used in developing the economic law—and used with the same degree of rationality as that attained in developing the astronomical law.

With regard to pragmatic opinions which rate scientific researches in terms of their effects, incomplete and even earlier studies of little understood but important phenomena may have more far-reaching and beneficial effects than studies of higher quality that deal either with inconsequential matters or with matters already well understood in their essentials. Great works of compilation may be rated very high from the pragmatic point of view, because of the many practical purposes they serve and the stimulus they furnish for the development of scientific theories. Pragmatic opinions also largely fashion the response of the scientific worker to group motives, and here Dr. Wright stresses obstacles which anti-scientific practices arising from such motives offer to the advancement of science. Three types are indicated: the wilful distortion of truth to mislead rival groups; suppression of the results of scientific research to prevent rivals benefiting by them; and use, as in war, of the results of scientific research to injure rival groups. Ethics and science, he holds, are inextricably linked, and unethical practices are not only anti-social but also anti-scientific. Again, he urges that the advancement of science demands the continuous discovery of new truths and the continuous development of new hypotheses, for which the fullest and freest possible interchange of knowledge is prerequisite. Dealing briefly in conclusion with the effects of war on science and with the reconstruction of scientific endeavour after the War, Dr. Wright admits that war may lead to rapid advances along certain specific lines of research, but suggests that the transition problems may be even more difficult than those in waging war itself. He urges concentrated effort to forestall the loss or destruction of the masses of information accumulated for war-time purposes.

## Incentives in Industry

IN an address to the Leicester Centre of the Institute of Industrial Administration on "Incentives for Indirect Workers" (*J. Inst. Indust. Admin.*, 5, 14; 1944), Mr. Harold White gives an interesting analysis of the incentives affecting workers not directly engaged in manufacturing processes or the assembly or finishing of products. After discussing the characteristic features of the indirect worker's job, he indicates seven types of incentive—particular interest in the type of work, personal pride in the apparent importance of the position held, increase in rate of pay, opportunities for promotion, bonuses based on earnings of direct workers, *ex gratia* bonuses, and permanency of position—the effectiveness of which depends largely on the intelligence and ambition of the individual and the general nature of his job. Factors on which actual bonus schemes have been based are next considered, and Mr. Whitehead's review of these schemes leads him to six conclusions, as follow. The big majority had proved sufficiently satisfactory to be considered a permanent feature of the company's policy. The more direct the bonus to the indirect worker, the better the response. Confidence in the management is essential to the success of a scheme. 'Ready-made' schemes are dangerous; no standard programme of incentives can be laid down for adoption without studying and evaluating internal circumstances. An incentive plan for indirect workers cannot be established by intuition: it demands thorough and careful forethought. The probable results, in cash, to the indirect workers must be fully considered, so that the probable amount is a real incentive, and not merely a financial liability to the company.

## Science in Post-Primary Education

AN interim report has recently been compiled by the Association of Women Science Teachers with the view of submitting a scheme for the teaching of science in the post-primary schools of the future (An Interim Report of a Sub-Committee of the Association of Women Science Teachers. Pp. vi+22. London: John Murray, 1944. 1*s.* 3*d.* net). The sub-committee which submitted this report considers the needs of all types of children within the secondary school range, dealing fully with the ideals that should permeate the science teaching and with the need for a change of outlook. Although the present publication outlines full syllabuses for children of eleven to sixteen years only, a subsequent publication, already in preparation, will also contain chapters on sixth form science, part-time education in science, the training of teachers and administrative problems. A useful chapter on laboratories and equipment, the museum, first aid, organization of department and other matters will be appended.

The five-year course of general science suggested is based on the fundamental principles of social relationships; selection from the syllabuses, by the teacher, will be necessary, as these syllabuses are thought to contain the maximum for children of the highest intelligence, given the best opportunity. For the first two years, the topics considered are the universe and its attributes of light, heat and gravitation, water, air, land and people; for the last three years those of energy, matter and life. Methods of presentation are discussed and time allowances for science recommended. A progressive outlook has produced syllabuses that are less academic than usual, although the experimental and objective attitude to problems is regarded throughout as of paramount importance.

## Royal Institution

DR. L. R. G. TRELOAR delivered a discourse at the Royal Institution on December 15, speaking on "Rubbers and their Characteristics: Real and Ideal". He pointed out that although rubbers are diverse in chemical constitution, they all conform to a general type of molecular structure, and it is in this structure that the origin of the remarkable physical properties of rubbers is to be found. All rubbers are built up of enormously long chain-like molecules which are linked together so as to form a loose three-dimensional network. The atoms of the molecular chain are in a state of continuous motion, due to their thermal energy; hence the molecule tends to take up a randomly-kinked, continuously fluctuating form, in which its effective length is only a small fraction of the full chain-length. As a result, the molecule exhibits elasticity. The elasticity of rubbers, like that of gases, is thus kinetic in origin. Rubber-like elasticity is always limited to a certain range of temperature, varying with the chemical constitution of the molecule. At low temperature, rubbers are transformed to a glass-hard condition, whereas at high temperatures they tend to lose strength and to approach the condition of a highly viscous liquid. In some rubbers, also, a crystalline state is possible. Crystallization develops slowly in

natural rubber at low temperatures, but it may be produced almost instantaneously by stretching at normal temperatures. Crystallization profoundly affects the physical properties of rubber, and its study has had an important bearing on the elucidation of its molecular structure.

### White Rainbow at Malvern

AN account of a white rainbow has been received from Mr. R. H. Stevens of "Rockland", Cowleigh Road, Malvern. The bow was seen at about 10.30 a.m. on November 8 after a short snowstorm, but no snow could be seen to be falling at the time of the observation. The white rainbow, also known as the 'fog-bow' or 'Ulloas Ring', is a rare phenomenon due, as in the case of the ordinary coloured rainbow, to refraction and reflexion of sunlight in falling drops of rain, but the raindrops composing the cloud must be very small—0·1 mm. or less in diameter. When this is the case, the first maxima of intensity for the different colours of the spectrum are spread out over a wider angle than with the larger drops, and are nearly coincident, the result being approximately to restore the original colour of the sunlight. The bow is only bright enough to be visible in exceptionally favourable circumstances and when the observer is near the cloud which contains the small drops. In this instance the previous occurrence of snow must be assumed to have been fortuitous, the snow probably having originated from clouds at a higher level than that of the cloud which carried the water drops.

### Recent Earthquakes

DURING August 1944, five strong earthquakes were registered by the seismographs at the Dominion Observatory, Wellington, New Zealand. The first of these, on August 8, from an estimated epicentral distance from Wellington of a little more than 48°, had a depth of focus near 80 km. Those of August 15, 25 and 30 all had a depth of focus near 100 km. In addition, thirteen earthquakes and tremors originated in or near New Zealand during the month and were felt by people in the Dominion. The strongest of these, on August 16, was felt with intensity 5 on the modified Mercalli scale in the region of Kahurangi Point. Others with intensity 4 were in the southern part of North Island on August 14; on the west coast of the North Island—Wanganui—Wellington, on August 17; and in the Wairarapa and north Wellington region on August 26.

The United States Coast and Geodetic Survey in co-operation with Science Service and the Jesuit Seismological Association has determined the provisional epicentres of three earthquakes on September 23, October 2 and 6. The earthquake of September 23, which took place about 12h. 13·3m. G.M.T., had its epicentre near lat. 53·5° N., long. 160·7° E., which is in the Kamchatka Peninsula. It was reported as registered by fourteen seismological stations. The earthquake of October 2 at 17h. 21·9m. G.M.T. had its epicentre near lat. 14·5° N., long. 90·1° W., which is in Guatemala. The shock of October 6 at 2h. 34·7m. G.M.T. occurred at lat. 39° N., long. 27° E., which is in Turkey. The earthquakes of September 23 and October 6 were registered by Mr. E. W. Pollard at his observatory at Binstead, Isle of Wight. Between August 2 and October 31, Mr. Pollard's home-made apparatus registered twenty-three earthquakes and tremors, mostly from large distances.

Recordings for the period October, November and December 1943 have just been received from Suva, Fiji. Altogether thirty-seven earthquakes were registered during the period. These registrations are most useful when taken in conjunction with those of New Zealand, Australia and America.

### Scientific Literature for Liberated Europe

AN appeal, signed by Sir William Beveridge, Prof. P. M. S. Blackett, Mr. E. Carter, Mr. J. G. Crowther, Dr. C. D. Darlington and Sir Richard Gregory, has been issued for literature dealing with advances made in Allied Countries during the War for dispatch to liberated Europe. In particular, French men of science need this material as quickly as possible. In Paris, there is gas and electricity for only one or two hours in the evenings, so that experimental work is scarcely possible. All material sent to France would be fully used. Literature would go to the Centre National de Recherche Scientifique in Paris, which is in touch with the whole body of French scientific workers. Single copies would be microfilmed, and films and abstracts distributed. Thus the greatest possible use could be made immediately of any periodicals that can be sent to them. Sets of journals and single copies should be sent to the Association of Scientific Workers, Hanover House, 73 High Holborn, London, W.C.1.

### Conference on the Place of Science in Industry

THE Division for Social and International Relations of Science of the British Association is arranging a conference on "The Place of Science in Industry" to be held on January 12 and 13 at the Royal Institution, Albemarle Street, London, W.1. The conference will be opened by Sir Richard Gregory, president of the Association, and there will be four sessions, at which the chair will be taken respectively by Mr. Ernest Bevin, Lord McGowan, Sir John Greenly and Lord Woolton. The subjects of the sessions will be: what industry owes to science, fundamental research in relation to industry, industrial research and development, and the future—what science might accomplish. A limited number of tickets will be available for the public other than members of the Association, and may be applied for at the office of the British Association, Burlington House, London, W.1.

### Announcements

DR. SIDNEY E. SMITH, who recently resigned from the presidency of the University of Manitoba to take up the appointment of principal of University College, Toronto, and executive assistant to the president of the University of Toronto, the Rev. H. J. Cody, will succeed Dr. Cody as president on July 1, 1945.

THE Langley Memorial Prize, value £21, is open to competition among officers of the Colonial Medical Service who are serving, or who have served, in West Africa. The prize will be awarded for a paper on (a) tropical medicine or surgery; (b) tropical hygiene and sanitation; or (c) tropical entomology and parasitology. Papers, which may consist of either published or unpublished work, should be delivered to the Secretary, London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1, not later than October 1, 1945.

# LETTERS TO THE EDITORS

## Penicillin in Yaws and Tropical Ulcer

PENICILLIN has not, up to the present, been extensively employed in tropical medicine. There is, however, evidence that, among other conditions, penicillin has an action in syphilis[1,2], on *Spirochœta recurrentis* infections in mice and on *Spirillum minus*[3] as well as possibly on *Leptospira icterohœmorrhagiœ*[4]. Evidence which is here presented shows that penicillin is of value in yaws and tropical ulcers, which form two of the greatest problems in tropical medicine. Ulcers during the present year, 1944, have, for example, been responsible for the loss of 30,000 men-days among West African troops.

A total of twenty-four cases of yaws in children has now been treated; two were primary, the remainder secondary. 50,000–100,000 Oxford Units have been injected intramuscularly over 12–24 hours. The results are dramatic, and nineteen cases were clinically cured in an average time of 6½ days.

In the two cases of primary yaws, complete cure with reversal of the Kahn test was effected within 7 days. In the secondary cases, the 'snuffles' disappeared, the papules desquamated and the typical yaw dried up and lost its yellow colour within 24 hours. Afterwards, within 2 to 10 days scabs had fallen off and the only stigmata of secondary infection were white or grey-brown scarred areas.

In one case where a severe bismuth stomatitis had developed in a child following 1·5 grains of 'Sobita', penicillin produced a rapid cure both of the yaws and the stomatitis within 48 hours.

Typical cases are as follows:

*Case* 11. *Akusa.* Female. Aged 9 months. Achimota Village. A case of large primary yaw involving almost the whole of the sole of the left foot. Kahn and Ide tests both positive. 100,000 units of sodium penicillin given over 24 hours, and penicillin ointment applied to sole. After 2 days the primary had decreased in size and was drying up. After 6 days the foot was healed. Kahn and Ide negative. The foot was re-examined after 15 days and was found to be perfectly healed; no secondary rash.

*Case* 17. *Fahti.* Female. Aged 12 years. Fulani Zongo Village. Primary lesion on left knee six months ago, which was still present: has had generalized papular rash for 4 months. Kahn and Ide tests both positive. 100,000 units of sodium penicillin given over 12 hours. Within 24 hours, distinct flattening of some of the papules, and in others early desquamation. After 10 days, site of papules denoted only by areas of hyperpigmentation and the primary site by a grey-brown scar. Kahn and Ide positive.

*Case* 18. *Owudu.* Male. Aged 2½ years. Fulani Zongo Village. Primary lesion on inner border of right thigh, 8 months ago. This was still present. Multiple secondary lesions for the last six months, the main sites being chin and neck, abdomen, perineum and occiput. Also had a running nose. Ide test positive. Spirochætes demonstrated from the yaw in large numbers. 100,000 units of sodium penicillin over 12 hours intramuscularly. Within 24 hours the primary lesion had dried up, and presented a pink glazed appearance and the snuffles had ceased. Within 48 hours, all yaws showed thinning and shrinking of their crusts, darkening and complete disappearance of the typical yellow colour, the whole giving an appearance as if the scab had been desiccated. Some lesions already showed separation at the periphery. By 5 days, all yaws had disappeared, leaving either a pale fairly sound skin at the site of the lesion, or a grey brown leathery surface. By 10 days there was no evidence of active yaws, and the only stigmata left were areas of scarring denoting the site of the original lesions. Ide test still positive after 21 days.

The serology has been followed up in all cases, though complete results are not yet to hand. In the two cases of primary yaws treated, healing, with complete reversal of Kahn, has been accomplished within seven days. In two cases of secondary yaws observed over six weeks, the Kahn and Ide tests have not been reversed.

The reversal of the Kahn test is in fact an academic point, for the main object of any mass treatment of yaws is to cause cessation of the active infection. The indications are, however, in the light of the work of Wise and Pillsbury on syphilis, that larger doses of from half to one million units would effect the reversal of the serological tests. With larger supplies of penicillin available it is hoped to employ bigger dosage. Even with the small doses at present used, the disappearance of lesions is far more rapid than with 'Sobita'. There have been no toxic results even in quite young and very under-nourished children or in the nine cases where calcium penicillin was used intramuscularly.

Thus since *Spirochœta pertenue* is apparently also among the organisms susceptible to penicillin, it was decided to employ penicillin in phagædenic tropical ulcers, in which spirochætes and fusiform bacilli are present together with other organisms.

Many of the ulcers had been in existence for periods up to one year. A total of 35 cases has been treated, and six have healed completely within 7–35 days, while the rest, still under surveillance, are in process of healing. Here again, 100,000 Oxford Units were injected in twenty-four hours and penicillin ointment (250 units per gram) was applied, or penicillin ointment alone locally was used. Within forty-eight hours, there is a marked reduction in the pus, with disappearance of smell and rapid formation of granulation tissue in the base of the ulcer and a blue line of commencing epithelization at the edge. The œdema subsides; the surrounding hyperpigmentation of the skin also tends to disappear. The subsequent course of events is a rapid surface epithelization of the edges with filling up of the base of the ulcer with granulations. Within a few days the ulcer becomes sterile or shows only scanty organisms (occasionally spirochætes only), though in five cases *Ps. pyocyanea* has been found to be present but with no apparent inhibition of healing. Better results are obtained by a combination of local treatment and parenteral injection than local treatment alone.

Typical cases:

*Case* 2. *Adisah.* Female. Aged 30 years. Fulani Zongo Village. Large ulcer 5 cm. × 2 cm. and 1 cm. deep, with a chronic rolled edge of one year's duration. Spirochætes, fusiform, vibrios, staphylococci and anaerobic streptococci in the pus. Calcium penicillin ointment applied daily through the treatment. Within 48 hours, the edge was sodden and white coloured. In 3 days, the white detritus at the edge had been replaced by a blue line of epithelium, while the base was filling up with granulation tissue. By 7 days the cavity was nearly filled with a clean red granulation tissue and *Ps. pyocyanea* was cultured. At 21 days there was a central core of granulation 3 cm. × 1 cm. surrounded by a zone of soft white scar tissue. 24 days, almost healed, central area covered by a pink shiny epithelium.

*Case* 14. *Ghartey.* Male. Aged 10 years. Winneba. Ulcer on left internal malleolus 0·5 cm. in diameter, of one month duration. Smear and culture, fusiform bacilli and spirochætes, virios and anaerobic streptococci. Calcium penicillin was applied for 3 days only. After 7 days a blue line of epithelium had extended 0·5 cm. from the edge. Smear showed no organisms. Examined at 28 days—had been away from hospital with original dressing for three weeks. Despite this, only small central granulations were present about 2 mm. in diameter. Smear showed fusiforms and spirochætes. Penicillin ointment re-applied and within another 7 days the ulcer healed.

*Case* 15. *Kwasi Bentum.* Female. Aged 5 years. Winneba. Foul-smelling saucer-shaped ulcer of the right arm, 10 cm. × 5 cm., of 9 days duration; showed grey-green membrane with hæmorrhages. Smear and culture yielded fusiforms, spirochætes, vibrios and anaerobic streptococci. 100,000 units of sodium penicillin were given over 12 hours intramuscularly. After 24 hours the smell had gone, the edges flattened and the base of the ulcer cleaner though still unhealthy-looking; after 5 days, ulcer closing rapidly due to advancing epithelization from the edges. 15 days healed; 22 days, sound scar.

Two severe cases of cancrum oris in children have been treated; in both cases the lesions rapidly cleared both clinically and bacteriologically; one small boy suffering from extreme marasmus and

vitamin B complex deficiency unfortunately died a fortnight after the local condition had healed; the other patient recovered.

The impression has been gained that penicillin treatment gives the initial impetus to healing of phagædenic ulcers of several months duration; once healing has started, the subsequent course of events is controlled by the nutrition of the patient. It is to be noted that all our cases were ambulatory and all were under-nourished.

## Bacteriostatic Action of Sulphonamide Derivatives

WE have confirmed and extended the observations of L. K. Wolff and H. W. Julius (1939) that sulphanilamide acts on bacteria only when they are multiplying, that is, in the logarithmic phase of their growth. Taking into consideration the physicochemical changes which are apparent in the environment of bacteria rapidly subdividing, more especially the rapid fall in potential which accompanies multiplication, we have looked for a reducing agent and have found that about the time when the sulphonamides begin to act *in vitro* a substance is produced which gives the *o*-dinitrobenzene test applied by Fearon and Kawerau (1943) to the recognition of dienol compounds. This substance is of the nature of, and may be identical with, reductone.

Reductone readily condenses with *p*-aminobenzoic acid, sulphanilamide, sulphapyridine and sulphathiazole to form coloured compounds. We have isolated these compounds in crystalline form by adding the appropriate aminobenzene derivative to solutions of glucose which have been heated with alkali and then made acid according to the method used by H. von Euler and co-workers (1933) for the preparation of reductone. On account of its solubility, the sulphanilamide - reductone compound has not yet been obtained pure; but the other derivatives have been separated completely from the added aminobenzene compound.

From a study of the properties of these reductone derivatives, we have arrived at certain conclusions as to the role of *p*-aminobenzoic acid in bacterial metabolism and the way in which it is supplanted by the sulphonamides. The *p*-aminobenzoic acid - reductone compound goes into solution readily at a *p*H of 7·5–8·0, giving a yellow solution in which it undergoes rapid hydrolysis, even at room temperature, setting free *p*-aminobenzoic acid and reductone. When completely hydrolysed the solution is colourless. The sulphapyridine and sulphathiazole compounds are much less soluble than the *p*-aminobenzoic acid compound, and hydrolyse slowly and incompletely. From these and other observations it is concluded that the function of *p*-aminobenzoic acid in bacterial metabolism is to condense with, stabilize and temporarily immobilize prior to utilization, reductone or compounds of the reductone type which play an essential part in the chain of metabolic reactions and which, without such stabilization, would, by reason of their reactivity, be either lost to the bacterial cell or toxic to it. If compounds of the sulphonamide type be presented to the cell, they compete with *p*-aminobenzoic acid for the reductone produced during metabolism, and form with it compounds which are not available for use by the micro-organism.

In support of this view the following are some of the experimental results which we have obtained:

(1) Growth of streptococci has been observed on supplying the *p*-aminobenzoic acid - reductone compound to a medium, deficient in energy sources, which otherwise failed to give growth.

(2) No growth has been observed when the sulphapyridine - and sulphathiazole - reductone compounds have been substituted in the above experiment.

(3) Bacteria can be shown to assimilate added *p*-aminobenzoic acid from their environment, especially during the most active phase of growth. At a later stage of growth they return it once more to the surrounding medium.

(4) Bacteria also assimilate and later liberate added sulphanilamide, sulphapyridine and sulphathiazole, but not so rapidly.

Full details of this work will be published elsewhere later.

## Mode of Action of Benzylamine Sulphonamide ('Marfanil')

THE antibacterial agent benzylamine-4-sulphonamide (I), which under the name of 'Marfanil' was supplied in quantity to Rommel's forces in North Africa, has given interesting results in Allied hands (cf. Mitchell, Rees and Robinson[1]). Organisms made resistant to sulphanilamide by growing them in contact with the drug were resistant to all other sulphonamides except 'Marfanil'[2]. Schreuss found that the antibacterial action of 'Marfanil' was not antagonized by *p*-aminobenzoic acid[3]. A possible reason for these differences from the sulphanilamide-like drugs is revealed by the determination of the basic strength.

Benzylamine sulphonamide, having the amino-group insulated from the benzene nucleus by a methylene group, should be a much stronger base than sulphanilamide and *p*-aminobenzoic acid, which were found to be very weak bases[4]. Following the procedure outlined in the previous communication[4], the negative log of the acidity constant ($pKa$) expressing the position of the equilibrium of the reaction

$$BH \rightleftharpoons B + H^+$$

(where $B$ represents the base) was determined by potentiometric titration with the glass electrode in water at 20° C. (see table). Benzylamine-4-carboxylic acid (II), which stands in the same structural relationship to benzylamine sulphonamide as *p*-aminobenzoic acid does to sulphanilamide, was investigated also.

(I)  (II) 
If the forces between enzyme and metabolite or drug are electrical in nature, then similarly charged ions are overwhelmingly best fitted to compete with one another for the enzyme. However, the fact that substances with both acid and basic groups exist in solution as an equilibrium mixture of the four different electrical forms, in the proportion determined by the $p$H and the $p$K$a$, would render all substances in the accompanying table capable of competing with one another to some extent; but when a substance intended to displace an essential metabolite from an enzyme is mainly in a different electrical form from the metabolite, then the concentration required for its action may be so high as to exclude its use as a drug.

| Substance | $p$K$a$ (basic group) | $p$K$a$ (acid group) | Principal ionic form at $p$H 7·3 |
|---|---|---|---|
| Benzylamine-4-sulphonamide (I) | 8·18 | 10·23 | cationic |
| Benzylamine-4-carboxylic acid (II) | 9·64 | 3·59 | zwitterionic |
| Sulphanilamide (for comparison) | 2·1 | 10·3 | unionized |
| $p$-Aminobenzoic acid (for comparison) | 2·2 | 4·9 | anionic |

Applying the Mass-Law equation

$$p\text{H} - p\text{K}a = \log \frac{[B]}{[BH^+]},$$

one deduces that, at the physiological $p$H value (7·3), benzylamine sulphonamide exists mainly in the form of positive ions, whereas sulphanilamide exists as uncharged molecules plus a small proportion (0·1 per cent) of negative ions (this proportion increasing as the potency of sulphanilamide is increased by substitution, as in sulphathiazole and sulphadiazine[5]). Similarly, $p$-aminobenzoic acid exists mainly as negatively charged ions. Thus it is unlikely that benzylamine sulphonamide can compete effectively for the same position on the enzyme surface as the oppositely charged $p$-aminobenzoic acid.

Accordingly, it is postulated that benzylamine sulphonamide acts on a different enzyme from that involving $p$-aminobenzoic acid. Whether benzylamine-4-carboxylic acid can antagonize the antibacterial action of benzylamine sulphonamide remains to be determined. This possibility is not excluded by the above results, but it will depend, of course, on whether benzylamine-4-carboxylic acid is an essential metabolite, as demanded by the Woods-Fildes theory.

The benzylamine-4-sulphonamide was prepared by Prof. A. K. Macbeth, University of Adelaide, and the benzylamine-4-carboxylic acid (new synthesis)[6] by Dr. A. Albert, University of Sydney, who are hereby thanked.

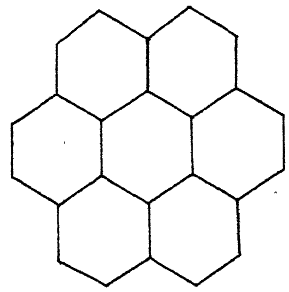
## Structure of Coronene

IN a recent communication[1], Robertson and White have reported provisional crystal structure determinations for coronene, $C_{24}H_{12}$. The molecule has great symmetry, as is shown by the figure. In view of the importance of this molecule in coal formation, some purely theoretical calculations I have made may be worth mentioning. Using the methods developed in an earlier paper[2], the energies of the mobile electrons have been computed in terms of the fundamental resonance integral β. From this it is easy to calculate the bond-orders and -lengths. The table below shows (i) the mean energy of the mobile electrons; (ii) the mean order of the C–C bonds; (iii) the order of the six central C–C bonds; (iv) the mean length of the C–C bonds; and (v) the length of the central bonds. Similar values are given for benzene and graphite. The last decimal place in the lengths is valid on a relative scale, but not on an absolute one. It may be added that the only experimental data used in this table are the lengths of the C–C, C=C and C≡C bonds in ethane, ethylene and acetylene.



Coronene, $C_{24}H_{12}$

PROPERTIES OF THE CORONENE MOLECULE.

| | Coronene | Graphite | Benzene |
|---|---|---|---|
| Mean energy per mobile electron | 1·440β | 1·576β | 1·333β |
| Mean order of C–C bonds | 1·576 | 1·525 | 1·667 |
| Order of central C–C bonds | 1·522 | 1·525 | 1·667 |
| Mean length of C–C bonds (A.) | 1·406 | 1·417 | 1·389 |
| Length of central bonds (A.) | 1·418 | 1·417 | 1·389 |

It is evident from the table that coronene lies between benzene and graphite, being nearer to the latter. The central bonds are very similar to the bonds of graphite, though the mean bond-length is about 0·01 A. shorter. This confirms the provisional conclusions of Robertson and White.

Further details will be published elsewhere.

## Genetics of Woodlice

THE work of Howard and Vandel on the genetics of the terrestrial Isopoda are well known, and their erudite memoirs have opened up a new chapter in genetics. As illustrating the profound difficulties of the geneticist, the following facts are of interest. Unfortunately, I do not possess that knowledge of genetics to explain the following phenomena, but would gladly welcome some enlightenment.

Briefly the facts are as follows: I crossed a female specimen of *Armadillidium vulgare* Latr. var. *rufobrunneus* Cllge. with a male specimen of Howard's type *D*, with the ultimate result that I obtained a brood of 39 females and 7 males all referable to the type *D*. A female of this brood was crossed with the male parent and in due course I obtained a brood consisting of 28 females and 42 males, all referable to Howard's type *D*. A male and female of this brood were crossed, with the result that a brood was liberated consisting of 58 females all referable to the variety *rufobrunneus* Cllge., most of which died within two days of liberation from the brood pouch.

The above-mentioned facts may be briefly summarized as follows:

*Armadillidium vulgare*
♀ var. *rufobrunneus* × ♂ type *D*

Result 39 ♀ and 7 ♂ all type *D*
×
Result 28 ♀ and 42 ♂ all type *D*
×
Result 58 ♀ all var. *rufobrunneus*.

I should here like to express my best thanks to Dr. H. W. Howard and Dr. Hamilton E. Quick for their kindness in supplying me with material.

## Heredity, Development and Infection

PROF. J. B. S. HALDANE's[1] letter on Dr. Darlington's[2] interesting and provocative article calls for two comments. First there is, I think, no published evidence to show that reversion from climber to bush type in roses is due to an agent transmitted from the stock (incidentally it may be noticed that Crane and Lawrence's[3] account of their experiment on p. 178 of their book does not mention the type of stock on which the buds were grafted). Even assuming that the difference between the climber and bush type is due to a change in a plasmagene, the reversion of a percentage of the buds might be due to the somatic sorting out of two different types of plasmagenes such as sometimes happens with plastids.

Secondly, at least a few British geneticists have been interested enough in the work of Lysenko and his colleagues in the U.S.S.R. for them to try experiments similar to those of the Russian workers. As no results have been published, one can only conclude they were negative. Thus I personally have experimented with the narrow-leafed rogue of peas[4,5] which Darlington[6] suggests is due to a plasmagene (seeds of type and rogue were kindly given to me by Miss C. Pellew for this work). Grafts of type on type, type on rogue, rogue on rogue and rogue on type were made in the seedling stages, and the length and breadth of stipules at flowering time measured. No effect of stock on scion was found.

## Inheritance of the Keel in *Potamopyrgus Jenkinsi* (Smith)

THE keel, when present in the aquatic and parthenogenetic mollusc, *Potamopyrgus Jenkinsi* (Smith), can exist in many degrees of strength. It may vary from the faintest of lines on the shell to a well-marked spinous keel, this latter being the aculeate variety of Overton.

Robson[1] found that colonies may be all smooth, all keeled, or the two forms may co-exist. The keeled forms may persist for years in the same locality, though the proportion keeled may vary from year to year, sometimes dwindling to zero. Boycott[2], who also worked on this character, found strongly keeled (aculeate) colonies rather rare. Juvenile keeled snails from the field, grown to adult size in the laboratory, were indistinguishable from wild-born adults. He also found many grades of development in the keel, and the occasional occurrence in Nature of the discontinuous development of the character when the keel fades off to give a smooth body whorl.

Both Robson and Boycott bred keeled snails in the laboratory. Robson, using keeled snails and fresh water of different chemical compositions and brackish water, obtained only perfectly smooth offspring. Boycott, using aculeate snails from a freshwater colony near Criccieth, obtained some keeled snails (mostly faintly keeled). However, conditions did not permit any definite conclusions to be drawn about possible causative conditions, except that keeled offspring more often appeared in the 'bad' conditions of open-air aquaria or in cultures kept in rusty tins. In recent years, similar experiments have been repeated, and in fresh water the few positive results have, like Boycott's, been inconclusive.

In 1943 a locality was found near Christchurch, Hants, where smooth snails live in a small freshwater stream and aculeate snails in the brackish water stretch of the same stream. These aculeate snails, bred in jars with brackish water of salinity 0·175 per cent and algal-covered pebbles from their native brackish stream (called keel-inducing conditions below), yielded 100 per cent aculeate offspring. Under similar conditions keeled and smooth snails, kept together in the same jar, yielded both keeled and smooth offspring. These experiments have been successfully repeated and amplified this year, and some of the main results are summarized, pending opportunities for carrying out more precise work.

A glass jar was immersed in the brackish stream at Christchurch for the second half of April 1944. This jar, filled with stream water and using keeled snails as parents, yielded both smooth and keeled offspring. A precisely similar experiment, using a jar immersed for part of May, gave only smooth *F*1. A jar set up with keel-inducing conditions and three snails—one perfectly smooth and the other two with barely perceptible keels—yielded an *F*1 of smooth snails and snails with a well-developed keel. Under similar conditions, ten smooth snails from a hundred per cent smooth colony yielded only smooth offspring. Experiments were also made by keeping snails, offspring of keeled parents, under keel-inducing conditions for varying periods of the first part of their lives and then transferring them to smooth-inducing conditions. A batch thus kept for the first 28–35 days of their lives before transference yielded seven individuals, only one of which was keeled. Similarly, of twelve snails kept 35–42 days before transference to smooth-inducing conditions (and

which were smooth at transference), eleven developed keels of varying strengths, one remaining smooth. The keel-inducing influence thus seems to act during the first few weeks of life. Snails first showed the keel at the age of about seven weeks. Though the discontinuous development of the keel has not yet been produced in the laboratory, its natural occurrence, on one occasion at least, seems to be due to accidental change of conditions from keel-inducing to smooth-inducing.

From the above experiments it appears that *P. Jenkinsi* exists as both keeled and smooth genotypes. Further, since brackish water *per se* does not induce a keel, it seems that the environmental factor responsible for the appearance of the keel is Algal. Moreover, this agency needs only to act in early life to induce a keel for the rest of the life of the snail. The Alga probably acts partly in a quantitative manner to produce keels of strengths varying from a scarcely perceptible ridge to the fully aculeate form.

As already stated, the offspring obtained from jars immersed during April and May at Christchurch were a mixture of keeled and smooth and smooth respectively. These results may throw some light on the many negative results previously obtained in experiments on the inheritance of the keel. It appears likely that, especially in freshwater, the keel-inducing species of Alga may have a relatively short life under the laboratory conditions tried hitherto. Jars with a healthy growth of brackish water Algæ from Christchurch on pebbles yielded 100 per cent keeled offspring from keeled parents. In the above two jars, however, the Algæ only remained healthy for a short time, later forming a flocculent precipitate. The keeled snails in the April jar were older (larger) than the smooth snails. This may be significant as suggesting that the older snails were in the labile condition for keel production at a time when the keel-inducing Alga was still alive in sufficient quantity in the culture. It is to be expected that some smooth colonies will prove on breeding analysis to contain a proportion of genotypically keeled specimens.

I am indebted to Miss C. H. Popham, of Christchurch, for helping in the collection of field material and to Mr. Moffatt, of Hambleden, for facilities in housing experiments.

## A Method of Obtaining Tissue Cultures of Adult Fibroblasts

IN recent years we have made several attempts to infect tissue cultures of fibroblasts from chicks and fowls of various ages with the virus of Rous sarcoma No. 1. Although we were not satisfied that such infection can take place *in vitro*, we gained some experience in methods of obtaining tissue cultures of adult fibroblasts, which may be of interest to others.

Resting adult connective tissues did not give satisfactory cultures, and it was necessary to devise a method of setting up local connective tissue proliferation, and afterwards removing cells at various intervals of time. Methods involving open operations were avoided, because of the risk of airborne bacterial contamination. In our first experiments, we implanted various kinds of threads into the breast muscles of fowls and withdrew them after different time-intervals, together with proliferating cells that had become entangled in them. This method, though satisfactory up to a point, had the disadvantage of introducing foreign matter into the culture medium and was sometimes accompanied by infection. The most satisfactory method was as follows. Small glass capillary tubes, 1·5 cm. long and 2·0 mm. outside diameter, were implanted into the breast muscle of fowls by means of a trocar and canula. The tubes were open at both ends, but a constriction at one end allowed a knotted thread to be retained by the tube and served to withdraw it at the desired time. A small skin incision can be made before inserting the trocar and canula to reduce the risk of introducing organisms from the skin; but this was not found to be necessary if the skin was well prepared with 1 : 1,000 acriflavin in 50 per cent methylated spirit immediately before operation. After introducing the tubes through the canula, the latter can be withdrawn, leaving the free ends of the threads protruding from the wound. These can conveniently be tied together and anchored to the skin with a stitch which also closes the wound.

Such small tubes, when withdrawn after intervals of one to ten days, are found to contain fibrin clot invaded by fibroblasts and macrophages; they are, in fact, miniature tissue cultures. By breaking the thin capillary tube, the contents can easily be liberated for implantation into suitable culture medium in roller tubes or other type of tissue culture apparatus. The method has the advantage of simplicity, and reduces handling with consequent risks of infection by airborne organisms. Cultures obtained in this way were maintained for about two weeks on fowl plasma desiccated embryo extract medium without the addition of any living cells.

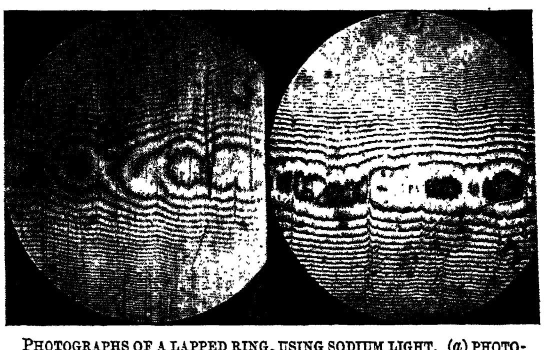
## Silvered Mirrors for Interferometric Measurement

THE simple interferometric devices used in Great Britain[1] and on the Continent for testing the surface quality of workpieces of less than 20 micro-in. surface roughness have recently been improved by applying a partly reflecting mirror as suggested by L. Leinert[2]. This method has been compared with



PHOTOGRAPHS OF A LAPPED RING, USING SODIUM LIGHT. (*a*) PHOTOGRAPHED THROUGH AN ORDINARY GLASS COVER SLIT; (*b*) PHOTOGRAPHED THROUGH SILVER SPUTTERED MIRROR. MIRROR BY COURTESY OF MESSRS. C. J. WHILEMS, LTD., ILFORD OPTICAL WORKS, FORREST ROAD, BARKINGSIDE, ESSEX.

the usual practice of using non-silvered glass[1] and the results are quite interesting. Whereas with non-silvered glass the interference bands are relatively weak and the underlying surface with its imperfections is easy to recognize, the silvered glass of the same surface shows the outlines of the interference bands very clearly (see accompanying reproductions). This is due to the fact that in this case the scattered light from the workpiece cannot penetrate the silver layer. A much better topographic picture of the surface is thus obtained; but it is open to question whether for practical inspection purposes a combined picture of surface and interferences would not be more desirable.

## Significant Figures of Numbers in Statistical Tables

IT is a well-known fact that most numbers in statistical tables start with a small digit. For example, in population tables almost one third of the entries begin with the digit 1. The same holds true for most tables of the type occurring in the World's Almanac.

A rough qualitative explanation of this fact can easily be given. If we consider tables in which the entries become rarer the larger they are, we can draw the obvious conclusion that in any interval, say, between 10 and 99, or 10,000 and 99,999, there are more entries on the small side than on the large side.

The quantitative aspect of this phenomenon requires a more detailed discussion. The study of a large number of tables shows that of all entries the fraction which begins with the digit 1 is given by $\log_{10} 2/1 = 0{\cdot}301$, beginning with 2 it is $\log_{10} 3/2 = 0{\cdot}176$, and, in general, the fraction with $p$ as its first digit is $\log_{10}(p+1)/p$. This quantitative behaviour has been studied in detail by Benford[1]. In spite of his investigation, Benford appears to arrive at the conclusion that this logarithmic distribution of the first digits is some natural phenomenon which he calls the "Law of Anomalous Numbers". In reality there is nothing profound about this 'law' and it is certainly not connected with the observation that "Nature counts $e^0$, $e^x$, $e^{2x}$, . . . and builds and functions accordingly". It is merely the result of our way of writing numbers, as we shall demonstrate below.

Consider an arbitrary table with a large number of entries which either are all positive or else are considered without regard to sign. Let $f(x)dx$ be the fraction of entries in the interval between $x$ and $x + dx$; then

$$\int_0^\infty f(x)dx = 1. \quad . \quad . \quad . \quad . \quad . \quad (1)$$

If the basis of our number system is $A$, for example $A = 10$, we shall write each entry $x$ of the table in the form

$$x = pA^m, \quad . \quad . \quad . \quad . \quad . \quad . \quad (2)$$

where we take

$1 \leq p < A$; $m$=integer: positive, negative or zero. (3)

In this way $p$ is a continuous variable which can be used to indicate the first digit of the number $x$; for example, if $p$ is between 3 and 4, the first digit of $x$ is a 3. More generally, $p$ gives the significant figures, $m$ the order of magnitude. We want to know what fraction of the entries has the value of $p$ lying in a small interval between $p$ and $p + dp$. For a fixed value of the exponent $m$ this is given by

$$f(x)dx = f(pA^m)\, A^m dp. \quad . \quad . \quad . \quad . \quad (4)$$

We must next sum this over all values of $m$, and the required fraction becomes

$$F(p)dp = \sum_{m=-\infty}^{m=+\infty} f(pA^m)A^m dp \quad . \quad . \quad . \quad (5)$$

This equation represents the mathematical formulation of the process of 'counting the first digits' of the entries in the table. If we integrate Equation (5) over $p$, between 3 and 4 say, we get the fraction of entries starting with the digit 3.

We next estimate the sum in Equation (5) by approximating it by an integral

$$F(p) = \sum_m f(pA^m)A^m \cong \int_{-\infty}^{+\infty} f(pA^m)A^m dm. \quad . \quad (6)$$

This integral is easily evaluated, for by substituting again the expression for $x$,

$$x = pA^m,\ dx = pA^m \ln A\ dm, \quad . \quad . \quad . \quad (7)$$

we find using Equation (1):

$$F(p) \cong \int_0^\infty f(x)dx/p \ln A = 1/p \ln A \quad . \quad . \quad . \quad (8)$$

The fraction of entries which have $p$ in an interval from $a$ to $b$ is

$$\int_a^b F(p)dp = (\ln b - \ln a)/\ln A = \log_A \frac{b}{a} \quad . \quad (9)$$

By taking $A = 10$ and $a$ and $b$ two consecutive integers, we have the required distribution law. The main point in this derivation is that the integral in Equations (6) and (8) is independent of the function $f(x)$, that is, independent of the distribution of the magnitudes of the entries in the table. The logarithmic distribution of the first digits has nothing to do with the nature of the entries in the table or with their distribution.

One important question has still to be considered, namely, how accurately the integral in Equation (6) approximates the sum. The answer to this question does depend upon the properties of $f(x)$. It is thus easy to find examples of tables for which the logarithmic distribution of the first digits is not true, by choosing $f(x)$ in such a manner that the sum differs widely from the integral; this is so, for example, for a table of populations of places with five thousand or more people, in which almost as many entries occur with first digit 5 as with first digit 1. Moreover, the range of most tables is not very large, and therefore the sum over $m$ for any one table contains only a few terms. The observed agreement is probably improved by the fact that we integrate between two integers $p$ and $p + 1$, which presumably has a smoothing out effect.

$A = 10$

| First digit | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 |
|---|---|---|---|---|---|---|---|---|---|
| Actual | 636 | 341 | 256 | 211 | 168 | 154 | 130 | 111 | 102 |
| Expected | 635 | 371 | 263 | 205 | 167 | 141 | 122 | 108 | 97 |

$A = 100$

| Number of digits | odd | | | even | | |
|---|---|---|---|---|---|---|
| First digits | 1 | 2, 3 | 4–9 | 1 | 2, 3 | 4–9 |
| Actual | 359 | 309 | 396 | 277 | 288 | 480 |
| Expected | 317 | 317 | 420 | 317 | 317 | 420 |

Some of the questions connected with the approximation of the sum by the integral are discussed in another communication by Furry and Hurwitz[2]. It is

obvious that the approximation will be good for sufficiently small $A$ and poorer for larger $A$. This is illustrated by counts of a group of population tables using first $A = 10$ and then $A = 100$, as shown in the tables. The expected numbers are calculated from Equation (9). In this case $A = 10$ is small enough for the agreement to be good ($P(>\chi^2) \simeq 0 \cdot 77$ on Pearson's test of goodness of fit), but $A = 100$ is not ($P(>\chi^2) \simeq 0 \cdot 0003$).

## Observations on Bird Behaviour

DR. K. G. BRITTON has recently described the behaviour of "a deluded sparrow"[1]. I can quote an almost identical case which happened some years ago. Early one summer morning I was awakened by a cock house-sparrow pecking violently at my bedroom window, which faced nearly due east. This was repeated the next morning. Between onslaughts at the window glass the sparrow clung to ivy which covered the deeply recessed sides of the window. This continued for a week, after which time the sparrow disappeared.

Dr. Britton draws interesting implications from the experiments and observations he made, namely, (*a*) mental maladjustment of the sparrow, (*b*) the possibility of intelligence well above the instinctive level. I should like to add collaborative examples of both postulates.

(*a*) *Mental maladjustment*. A hen blackbird nested in our garden and successfully reared two young ones. When these no longer required feeding, she continued for two or three weeks to offer food to any bird, adult or fledgling, that came near her. A young thrush accepted food, and once, when the blackbird offered a worm to an adult robin, it accepted this, whether from surprise or intention one cannot tell.

(*b*) *Intelligence*. The parents of a family of fledgling house-sparrows brought their young to feed on a supply of crumbs which we placed regularly on our verandah. When the parents ceased their care of the young sparrows, the latter continued to come by themselves. It was soon possible for us to recognize two individuals among them. One held its head on one side and the foot and leg of the other side were partly paralysed. The bird was timid, stupid and at a disadvantage. The second was a hen bird: in time we learnt to recognize her by slight individualities of proportion and colouring; but before this her behaviour distinguished her clearly. She took charge of the cripple, led it to food, and encouraged it by chirp and by suitable feeding movements. One day, as we sat very still in the lounge, with the door leading on to the verandah open, the young hen led her 'afflicted brother' through the door and across the floor to crumbs fallen under the table. She watched him feed and escorted him back to safety again.

It is usually stated that all bird behaviour is instinctive. Much of it can, of course, be adequately described by this term. It seems inadequate, however, to speak as though the whole of animal behaviour, vehicled through such diverse types of nervous systems, can be classified under one of two terms—instinct or intelligence. Such stultified and obsolete terminology has long since been advanced upon by the psychologist dealing with human behaviour. Human psychology has developed terms for all the grades of specific psychic* phenomena. In our opinion biologists are hampered by this paucity of psychological terms, a condition which tends to mask instead of to clarify the ideas at issue. No doubt fuller terminology has been developed by specialist workers, but nothing of the kind is used by biology or natural history at large.

* Using the word in its legitimate sense.
[1] *Nature*, 153, 559 (1944).

WITH regard to the cock house-sparrow reported in *Nature* of May 6, 1944, as continually attacking its own reflexion in a glass window, a peacock of mine was a great nuisance because he would fight himself, in windows and the bright parts of cars. I have seen a cock house-sparrow attacking a window, and cases have been reported to me of a male blackbird, chaffinch, robin, dipper (at a house near a stream) and a grey wagtail doing the same. In all these cases the bird appeared to mistake its reflexion for a rival male trespassing on its territory and strove long and steadfastly to expel the intruder.

## Wharton's Jelly Considered as a Conducting Path

IN connexion with the interesting discovery by Barcroft *et al.*[1] of the passage of molecules as large as serum albumin along the Wharton's jelly of the umbilical cord of the sheep, I beg to offer the following comments.

So far as the supply of nutriment (other than water) to the fœtus is concerned, in the late stage of development of the experimental specimens employed, namely, after the establishment of a fœtal vascular system and of its relation to the maternal endometrium, the transmission of large-sized molecules at a relatively slow rate along the Wharton's jelly may be considered to be only a minor method of nutritive supply compared with the rapid transmission of substances with smaller molecules by the blood stream. But the discovery of this function of the Wharton's jelly becomes of paramount importance, if we may postulate that, in the very early stages of development before angiogenesis has commenced, the primitive mesoblast, from which the Wharton's jelly is derived, has the same power to transfer large-molecule substances from the trophoblast (and hence from the endometrium) to the embryo. In this light, the early development of the primitive mesoblast in the monkey[2], and its even more precocious development in man[3,4], becomes of considerable significance.

## St. Jerome and Vitamin A

THE following passage, taken from St. Jerome's "Life of St. Hilarion", which was written about A.D. 392, appears to be the earliest account of the etiology, symptoms and cure of severe vitamin A deficiency. "From his thirty-first to his thirty-fifth year he had for food six ounces of barley bread, and vegetables slightly cooked without oil. But finding that his eyes were growing dim, and that his whole body was shrivelled with an eruption and a sort of stony roughness (*impetigine et pumicea quadam scabredine*) he added oil to his former food, and up to the sixty-third year of his life followed this temperate course, tasting neither fruit nor pulse, nor anything whatsoever besides."

This combination of an eye-affection, night-blindness or perhaps xerophthalmia, with a severe hyperkeratosis precisely resembles the condition described by Frazier and Hu[1] as occurring in Chinese patients who had received a diet not unlike that of St. Hilarion, namely, a cereal other than wheat, white cabbage and salted vegetables. These patients were speedily cured by cod-liver oil or carotene; and it seems probable that a crude and unpurified olive oil, such as St. Hilarion would have permitted himself, would contain enough of the fairly high vitamin A content of the olive to relieve his symptoms and maintain good health. The evident accuracy of St. Jerome in this particular may induce further study of this interesting biography.

## West Cumberland and its Utilization

As one who has had contacts, through geology, with industry, mining and agriculture in Cumberland during a quarter of a century, may I be permitted to comment upon Dr. Stamp's article on "West Cumberland and its Utilization" in *Nature* of November 18.

The basic causes of the depression in West Cumberland during the 'thirties are only too fully recognized, and lack of transport facilities cannot be regarded as one of them. Indeed, as the raw materials for the iron and steel industry are found within the district, the transport from mine to furnace and furnace to factory is almost eliminated.

Although West Cumberland does not lie on the western main route from England to Scotland, it is misleading to describe it as lying at the end of a branch line from Carlisle. It is connected with the main railway route at three places, Carlisle, Penrith and Carnforth. Admittedly the south route needs improving. The urgent need here is for a railway and road, across the Duddon Estuary, so quartering the road and rail distance between Askam and Millom.

The intense depression in the heavy iron and steel industries in the 'thirties was national, but in West Cumberland its effects were felt not only in the rolling mills, the blast furnaces and the coke ovens, but also in the local iron-ore mines, limestone quarries and coal mines, which supplied the raw materials for the heavy industries. The presence of coal, hæmatite and limestone in the same area are natural advantages enjoyed by West Cumberland, and to them we may add two more. Adequate water supplies are, or can be made, readily available. The district is served by ports, so that foreign hæmatite, when needed, comes into the district by the cheapest means of transport—transport by sea—and exports flow from the ports.

These natural advantages are beneficial during times of trade prosperity; but because the industries are so largely interrelated and interdependent, the whole district is especially susceptible to trade depressions. The need for new industries is self-evident.

Dr. Stamp's statement that under certain contingencies "the enormously important influx of wealth from holiday makers will cease" is difficult to understand. Alas, no such wealth has ever flowed into West Cumberland. West Cumberland should not be confused with the Lake District, from which it is quite distinct, both topographically and geologically. The present industrialization of the former district in no way affects the amenities of the latter, and the position would not be changed by bringing new industries into West Cumberland.

Whether the Lake District becomes a national park or not, the holiday resorts for this lovely district will continue to be largely centred on Keswick, Ambleside and Penrith, all far removed from the industrial West Cumberland. As regards the seaside villages on the West Cumbrian coast, these are primarily the holiday resorts of local people. Their prosperity will reflect the prosperity of the industrial area.

Everybody will agree that regional "planning is essentially the right allocation of land". In Cumberland the allocation would appear to be: land for industries in the industrial zone of West Cumberland, the minimum inroad by industry into the rich agricultural land surrounding Carlisle, and the reservation of the Lake District as a national park.

F. M. TROTTER.

Geological Survey,
Manchester.

I HAVE no quarrel with most that Dr. Trotter says, but his letter strikes just that note of false optimism which it was my concern to avoid. Apart from the steady deflexion of the hæmatite reserves, the heavy iron and steel industry is naturally well sited, but to say the "need for new industries is self-evident" is a long way from suggesting how they can be attracted. It is in this regard that a manufacturer seeking a location for, say, a textile factory, would look seriously at the time taken to reach an area off the main line by which his goods would be distributed. It is 1½ hours by rail to Whitehaven from Carlisle, 2¼–3 hours from Penrith and 2¾–3¾ hours from Carnforth. I was not, of course, confusing West Cumberland with the Lake District; but it is important to realize that the war-time extension of the industrial area has introduced an alien element in the once purely rural views from the high ground of the western Lakes. To say that the charming West Cumbrian coast from St. Bee's Head to Millom is primarily the resort of local people is to deny its immense potentialities as a natural seaside extension to the Lakes, which increased facilities of access and accommodation should render very popular and a consequent source of wealth to the area—but not if it is spoiled by sporadic industrialization.

L. D. STAMP.

# RAT PLAGUES IN WESTERN QUEENSLAND

By A. C. CROMBIE
Zoological Laboratory, Cambridge

PLAGUES of native species of rodent recur from time to time in the dry inland plains of Australia[1,2,3,4]. Palmer[3] describes an outbreak of rats (apparently the long-haired rat, *Rattus villosissimus* Waite[4]) which occurred after continuous rains during 1869–70, and moved northwards across the Gulf Country plains from the head of the Flinders River (Fig. 1). There was a corresponding increase in native dogs, snakes, hawks and owls which, together with the exhaustion of the food supply, the drying of the grass at the end of the season and their own cannibalism, brought the plague to an end. Evidence of previous plagues was found in "hollow trees, in which owls had lived for years, [which] were filled with the bones and skulls of millions of rats". Troughton[4] (p. 286) observed another outbreak of *R. villosissimus* on the Barkly Tableland in 1934. I have been unable to obtain records of plagues on the plains of Central Western Queensland further back than the beginning of this century; but since then *R. villosissimus* has erupted here at intervals of approximately eleven years, in 1907, 1918, 1930–31 and 1940–42. Each time the rats travelled in a roughly south-easterly direction. During April–June 1907 they moved at night on a 150-mile front south and south-east from the Flinders River, and were followed by large numbers of wild domestic cats and dingoes[1]. In this year, and in 1918, it was observed that practically all those trapped were males[1].

Several correspondents have kindly described to me the latest plague of *R. villosissimus* (identified by the Queensland Museum), which has recently subsided. Migration was not continuous. The rats took about two years to go from Boulia to the Thompson River at Longreach, a distance of about 200 miles. They were present in large numbers at Quilpie in March 1941. At a point $X$ (Fig. 1), the course of the plague was as follows. They had arrived at a place 60 miles north-west of $X$ about two months before they reached $X$ itself in fair numbers in December 1940. In January 1941, their numbers greatly increased and persisted at this level until about October of the same year. It is difficult to estimate the actual population density. Between 3 and 53 were caught per night in traps consisting of a tip-board which dropped the vermin into a large tub of water, a number of which were set round the verandahs of the house. The population decreased suddenly in December 1941, rose again in February 1942, and fell once more in April. The rats finally disappeared after the heavy, soaking rains of May 26, 1942, and very few were seen after that. They fed mainly on vegetable matter, destroying all the fruit and vegetables in gardens except, according to one correspondent, parsnips and members of the onion family. They would also eat meat, leather, etc., when they found it. Cannibalism was widespread. An observer at Boulia "was informed from reliable sources that 95% of the rats trapped were males". In plagues of *Mus musculus*[1] there was a preponderance of females before, and of males after, they began to migrate. The reason for the preponderance of males was apparently that they led the migrations and left no food behind them for females and young, which then resorted to cannibalism. All the above observations on *R. villosissimus* were made on migrating swarms.

All four rat plagues were followed by plagues of feral cats, which later died of disease and starvation. In 1931, the rats reached their maximum at $X$ in May, and the cats were dying in large numbers by September. On one occasion 73 cats were shot in a day about the house and garden at $X$. The number

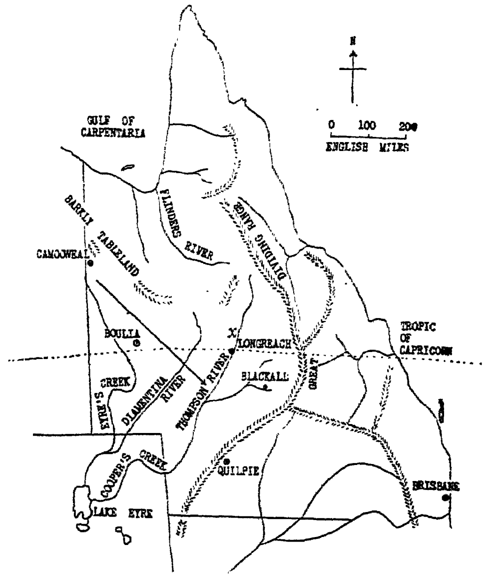

FIG. 1. MAP OF QUEENSLAND. THE ARROW SHOWS THE GENERAL DIRECTION OF THE PLAGUE OF *Rattus villosissimus* IN 1940–42.

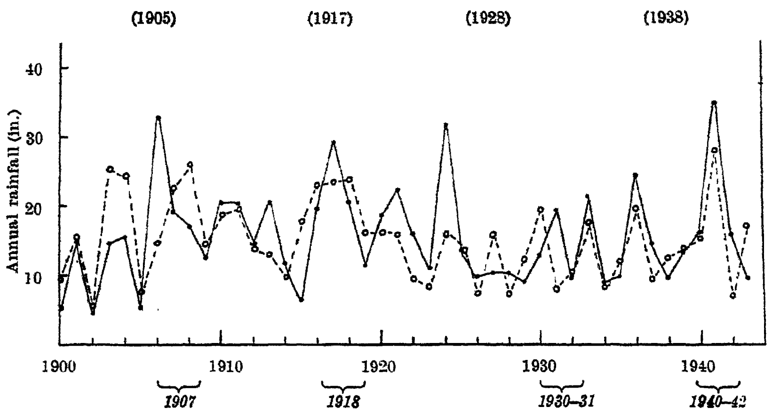

FIG. 2. ANNUAL RAINFALL AT LONGREACH (●) AND CAMOOWEAL (○) FROM 1900–43. IN GENERAL THE ANNUAL RAINFALL OF THE WHOLE OF WESTERN QUEENSLAND FOLLOWS THE SAME COURSE, BUT DECREASES FROM NORTH-EAST TO SOUTH-WEST. PLAGUE YEARS ARE SHOWN IN ITALICS. YEARS IN WHICH SUNSPOT MAXIMA OCCURRED ARE GIVEN IN BRACKETS ABOVE THE CHART.

of foxes increased enormously in 1941 and remained high until October 1942, when they began to die of canine distemper. The number of cats also rose rapidly at the beginning of 1942, but at the end of that year feline distemper caused a dramatic fall in population. Large numbers of cats were found dead or dying about the countryside during August and September. Ringworm was common in the cats in 1942 and was transmitted to station dogs and occasionally to children. These diseases would spread rapidly in such dense populations[5]. After the outbreaks were ended, rats, cats and foxes continued to exist at their normal low level of population.

There are in general three prevailing views about the cause of fluctuations in population[6,7]. (1) They may be attributed to climatic changes, such as when exceptionally favourable conditions allow a species to take advantage of its potentially rapid rate of reproduction[8,9,10,11]. (2) The inherent instability of populations of several ecologically related species may produce oscillations quite apart from environmental changes[12,13,14,15,16,17]. (3) Outbreaks may be due to unnatural conditions created by the activities of man. Fig. 2 shows that three of the four plagues described above were associated with exceptionally rainy seasons[18]. On the other hand, the plague years 1930–31 were not especially wet, while other wet years did not have plagues. It is possible that in 1930–31 temperature or other conditions may have favoured increase. MacLagan[19] has shown that over the last hundred years the frequency of outbreaks of several British insects is correlated with the periodicity of sunspots. The connecting link between sunspots and outbreaks is climatic. Each of the four plagues described above began within two years of the sunspot maximum immediately preceding it. It is possible that there may be some connexion between them; but the number of records is too few to establish either this or the contrary.

I wish to thank Mr. G. W. Moule, Government veterinary surgeon, Central West, for his kindness in sending some of the information quoted above; Mr. H. A. Longman, director of the Queensland Museum, for other information; and Mr. J. H. Pike, Agent-General for Queensland, for the loan of "Tables of Rainfalls in Queensland" (1933). My other correspondents will be nameless, but not unthanked.

# TROPICAL PASTURES

THE best grassland has depended for its existence upon a moderately cool and humid climate. Only a relative few of those familiar with the almost perpetual verdancy of English meadows and pastures realize the intensity of longing expressed in Psalm xxiii for *green* pastures and running waters seldom seen in a semi-arid land. In the tropics a high rainfall promotes the formation of acid soils, and a high temperature makes it difficult for most turfy grasses to form what inhabitants of temperate climates regard as a sward. Choice of tropical fodder plants is so limited that some varieties of sugar-cane are impressed into the class of forage grasses; and most of the tropical grasses are either tall and erect, or trail to make a tangled cover, neither type of growth being so amenable as that of the grasslands of Great Britain or of the temperate lands colonized by European pasture-species.

The difficulties of establishing a pasture in the tropics are added to by an apparent lack of suitable leguminous companion plants: no legume having properties corresponding to wild white or subterranean clover has been found.

Two recent Bulletins (Nos. 31 and 32) of the Imperial Bureau of Pastures and Forage Crops at Aberystwyth deal with pasture problems. No. 31 is entirely, and No. 32 partly, devoted to problems of management in the warmer countries. No. 32 ("Advances in Grassland Husbandry and Fodder Production: a Symposium") is a miscellany, ranging from an appreciation (with bibliography) of the scientific work of R. D. Williams to a review of field experiments at Potchefstroom and a note on the fixed oil of the seeds of *Trifolium subterraneum*. The articles are mainly reviews or abstracts, the 'symposium' thus being a gathering of varied information which might not otherwise have been published, or, if published, might escape the attention which the compilers seem to think it deserves. There is no common thread of interest.

Under the title "The Provision of Animal Fodder in Tropical and Subtropical Countries: Part One", Bulletin No. 31 gives a succinct account of experience and hopes in the West Indies, Hawaii, Fiji, the Gold Coast, Nigeria, the Anglo-Egyptian Sudan, Zanzibar and Pemba, and Southern Rhodesia. The information it gives will be valuable not only from the purely grassland aspect but also from sociological points of view, since for example in West Africa the potentialities of change in the type of husbandry are of high social importance. That is also true of the West Indies, and indeed the paper written by D. D. Paterson with assistance from other West Indian authorities is a masterly presentation in brief of the whole problem implied by an extensive establishment of good grassland in the tropics.

To find species that would grow at all under the given conditions has been the first thing, and with limited experimental resources it has been natural to neglect matters like those which have not received full attention in more highly developed areas.

Quality of herbage, and its effect upon livestock, is largely an open question in the tropics, few chemical analyses being available. Paterson remarks: "There can be no doubt that under tropical conditions the chances that the herbage may be lacking in some essential minor constituents are not less than in temperate countries. . . . After a spell in some of the other islands, racehorses reared in Tobago do not

stand up to the strain of the racecourse as well as they do in their home island". Pressure of research in other directions is given as the reason for deferment of intensive study of the role of minor elements; but it seems fair to ask why the question of nutritional quality should be taken so fatalistically. The salary of a chemist or two would surely not be too much to add to an ordinary budget of chemical or veterinary investigation, and in conjunction with a rational policy of land use and nutrition would probably yield a high dividend.

The bulletin contains a large number of suggestive facts. Fiji has no native grass, the so-called 'native' grasses being importations which have run wild. In view of the decline of the natural indigo industry, it is interesting to learn that the cultivation of a trailing species of indigo for fodder and for purposes of soil protection is actually on the increase. What is a pest in one part of the world may be a useful grass in other parts of the world—or, as in Hawaii, in another part of one island. HUGH NICOL.

## ECOLOGICAL PRINCIPLES AND FORESTRY

ON July 2, 1943, members of the forestry associations of Great Britain met at the invitation of the British Ecological Society to discuss problems arising from a paper by Sir Roy Robinson in *Forestry*, the journal of the Society of Foresters of Great Britain (see *Nature*, 152, 196; 1943). A fuller account of the meeting is now available (*Forestry*, 17; 1943).

Prof. A. G. Tansley, in opening the meeting, said he welcomed the desire for a closer contact between ecology and forestry. He thinks foresters would, through ecology, find much to help them to a scientific rationale of their practical operations. Prof. Tansley stresses that scientific ecology is a very young subject of research, almost entirely a product of the present century and only developed energetically since the War of 1914–18. It is in this newness of the subject that may lie the danger for the young forester. As is said, it has only been really developed since the War of 1914–18, and it is in this period that the word 'ecology' has come trippingly from the lips and pens of the young trained forester, the word being often made to serve as explanation for forestry processes as yet but dimly understood or assimilated by the junior. Prof. Tansley says: "I know very little of practical forestry, and I have often wished when I was teaching forestry students their elementary botany, and always from the general point of view of ecology, that I had had a practical training both in forestry and agriculture, just as I wished I had had a practical training in medicine when I was teaching biology to medical students. For just as scientific medicine is really a branch of applied biology, so forestry and agriculture may be regarded as branches of applied ecology."

To increase our knowledge of the ecology of woodlands, Prof. Tansley suggests a "continuous opportunity for access to and study of planting experiments together with the power of suggesting different variations and forms of control which are likely to lead to increased insight into the factors at work"—in fact, research work, which all foresters would welcome. It is, however, at present, a long step from this interesting and valuable work to the ordinary practical operations of the forester based on the growth of crops to produce marketable timber. Sir Roy Robinson's explanation that in afforestation work some species are pioneers and others are successors is obviously correct. But practical research is required to show how to shorten the experimental period in new afforestation work, if such a step is economically or ecologically possible from the financial point of view.

The experienced practical forester feels that a distinction should be sharply drawn between the true ecological research point of view and its work, and the practical sylvicultural activities of the executive forester who has to acquire a working knowledge of his soils in order to undertake his duties. In other words, the danger nowadays for the younger generations of foresters is that they may be led into sylvicultural inaction pending the outcome of the ecologists' experiments, giving the latter "the power to suggest different variations and forms of control" of the sylvicultural operations of the forester. The highly efficient sylvicultural management gradually brought into being in European Continental forestry departments was not attained by such means, though such research work will always prove of value to the sylviculturist when it has been brought to the point where its practical applications will obviously lead to better results.

## BIOLOGICAL STUDIES IN SOUTH AFRICA

THE *South African Journal of Medical Sciences*, published quarterly by the University of Witwatersrand and the South African Institute for Medical Research, is devoted to original work in any of the sciences represented in the medical curriculum. C. de V. Bevan contributes to the February 1944 issue (9, No. 1) an interesting article on the cultivation of the South African Rickettsiæ in developing chicks and the preparation of vaccines from the membranes of these. Dilute egg vaccines do not, he concludes, protect guinea pigs against epidemic infection, although they protect wholly against tick-borne infection and partially against endemic infection. Concentrated vaccines must be used in order to obtain complete protection against epidemic typhus produced by inoculation of guinea pigs with egg-passaged strains. A modified Machiavello technique for staining Rickettsiæ is described. The author finds that clearer staining is obtained if the smears are cleared in benzene. Bacteria and Rickettsiæ ground in a mortar with alundum are disintegrated. The development of the chick-embryo method will provide, the author thinks, smaller quantities of a far more potent vaccine than any that has yet been produced. The advantages of the egg-vaccine over the mammalian vaccines are discussed.

In the same issue, Margaret L. Creed discusses the nutritional value of a poor South African diet and of certain dietary supplements, and N. Sapeika reports on the digitalis action of a glycoside from the liliacean species *Urginea rubella*. More than twenty-five species of *Urginea* have been recorded in South Africa; many of these probably contain a toxic glycoside and a few are known to be toxic to stock. The issue concludes with a paper by O. S. Heyns and S. S. Hersch on the birth-weight of urban Bantu and the incidence among them of syphilis, still-birth and premature labour.

The Biological Supplement to this journal is published separately. The February 1944 issue includes a noteworthy article by C. J. van der Horst on further stages in the embryological development of *Elephantulus*, the affinities of which with the Insectivora and Lemuroidea relate this study to the embryology of the primates and of man.

Christine Gilbert records work on the development of the post-renal segment of the inferior vena cava in the same species. G. H. Roux gives a beautifully illustrated account of the cranial anatomy of the marine amphibian *Microhyla Carolinensis*. Protozoology is represented by a description, by A. J. Gibbs, of the life-history of the Adeleid coccidian *Chagasella* sp., found in the salivary glands of the plant-feeding Hemipteran *Cenœus carnifex*.

G. LAPAGE.

## FORTHCOMING EVENTS

### Thursday, December 28

ROYAL INSTITUTION (at 21 Albemarle Street, London, W.1), at 2.30 p.m.—Sir Harold Spencer Jones, F.R.S.: "Astronomy in our Daily Life", 1: "The Spinning Earth" (Christmas Lectures).

### Saturday, December 30

NUTRITION SOCIETY (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 11 a.m.—Conference on "The Nutritional Role of the Micro-Flora in the Alimentary Tract".

ASSOCIATION FOR SCIENTIFIC PHOTOGRAPHY (at Caxton Hall, Westminster, London, S.W.1), at 2.30 p.m.—Discussion on "The Choice of Materials for Scientific Photography" (Papers by Dr. H. Baines and Mr. F. J. Tritton).

ROYAL INSTITUTION (at 21 Albemarle Street, London, W.1), at 2.30 p.m.—Sir Harold Spencer Jones, F.R.S.: "Astronomy in our Daily Life", 2: "The Revolving Earth" (Christmas Lectures).

## APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

ANALYTICAL CHEMIST FOR THE METALLURGY DIVISION of the National Physical Laboratory—The Ministry of Labour and National Service, Central (T. and S.) Register, Room 5/17, Sardinia Street, Kingsway, London, W.C.2 (quoting Reference No. F.3304.A) (December 27).

DEMONSTRATOR or ASSISTANT LECTURER (temporary) in BOTANY—The Acting Registrar, The University, Leeds 2 (December 30).

SPEECH THERAPIST—The Director of Education, Education Offices, Woodlands Road, Middlesbrough (December 30).

TEACHER mainly for MATHEMATICS and ENGINEERING SCIENCE in the Junior Technical School and in Senior Day and Evening Classes—The Principal, County Technical College, Gainsborough, Lincs. (January 5).

ASSISTANT REGISTRAR—The Secretary, Bedford College for Women, Regent's Park, London, N.W.1 (January 6).

RADIO DEVELOPMENT ENGINEERS for the laboratory of a large electrical engineering works in the N.W.—The Ministry of Labour and National Service, Central Register, Room 5/17, Sardinia Street, Kingsway, London, W.C.2 (quoting Reference No. A.736.XA) (January 11).

UNIVERSITY CHAIR OF CONCRETE TECHNOLOGY tenable at Imperial College of Science and Technology—The Academic Registrar, University of London, c/o Richmond College, Richmond, Surrey (February 26).

PROFESSOR OF MATHEMATICS, and a PROFESSOR OF CHEMISTRY—The Secretary, Queen's University, Belfast (March 31).

LECTURESHIP IN MORAL PHILOSOPHY AND THE HISTORY OF PHILOSOPHY (including Greek Philosophy)—The Secretary, Queen's University, Belfast (April 30).

SPEECH THERAPIST—The Education Officer, Town Hall, Chesterfield.

LABORATORY STEWARD IN THE DEPARTMENT OF PATHOLOGY—The Secretary and Registrar, The University, Bristol.

# CIVIL SERVICE RECRUITMENT DURING THE RECONSTRUCTION PERIOD

THE report of the Committee of the Civil Service National Whitley Council on the staffing of the Civil Service during the reconstruction period, appointed in accordance with the Government's request as announced by the Chancellor of the Exchequer in the House of Commons on February 17, 1944, and containing proposals agreed between the official side and the staff side of the Council, has now been published*, under cover of a statement by the Government. The report proceeds on the basis envisaged in the Chancellor's statement that recruitment to the permanent service should begin at the earliest possible moment after the end of hostilities in Europe, continuing steadily throughout the reconstruction period, to provide for the required intake by departments of appropriately qualified men and women, and for the smooth transfer into permanent employment of those selected, whether from the Fighting Forces or otherwise.

In the covering statement the Government expresses its belief that public opinion will endorse the conclusion that, at the end of a war during which we have had total mobilization of man-power, a proposal to reserve all vacancies in the Civil Service exclusively for ex-Service candidates would be unfair to the rest of the community. The Government, however, is satisfied that the Committee's recommendation that, of the vacancies available for the reconstruction competitions, not less than 75 per cent in the administrative class, $66\frac{2}{3}$ per cent in the executive class, and 50 per cent in the clerical class should be filled by suitably qualified ex-service men, additional vacancies being reserved for ex-service women, constitutes the generous treatment that is essential, and the proposals in the report are commended to Parliament and to the public.

Like the Assheton Report on the training of Civil Servants, the recommendations of which have been accepted in principle by the Government, the present report is written almost entirely around the administrative, executive and clerical classes of the Civil Service. The importance of recruitment of well-qualified men and women to the professional, scientific and technical classes of the Civil Service is also recognized, and the Government states that departments employing these staffs are now engaged in formulating proposals for them which will, so far as possible, incorporate the principles already recommended for the general classes. It is expected that the matter will shortly be sufficiently advanced for discussion with the Civil Service staff representatives through the National Whitley Council. Meanwhile, the Government has decided to retain a central body of economists and statisticians, such as has been set up during the War in the Cabinet Offices. It is

* Recruitment to Established Posts in the Civil Service during the Reconstruction Period: Statement of Government Policy and Civil Service National Whitley Council Report. (Cmd. 6567.) Pp. 24. (London: H.M. Stationery Office, 1944.) 4*d*. net.

also stated that discussions are taking place in the National Whitley Council on problems that will arise on redundancy as the work of departments contracts, and on the question of any changes required in the main structure of the Service, such as the grades and classes, the methods of passing from one class to another, and the general arrangements to secure that the best use is made of all members of the staff. The flexibility of existing superannuation arrangements, the position of unestablished staff, and the effect of the new scheme of social insurance on the pensions of the public services have already received preliminary consideration.

The recommendations of the present report fall into two parts: those relating to "reconstruction competitions" and those relating to "normal competitions". The former are recommended primarily for those who have lost opportunities of competing for the Civil Service owing to the War, and the latter for those who reach the normal ages of entry as recruitment is re-opened.

The reconstruction competitions should extend over a period, so that the last man released from the Forces or other war service has as good a chance of competing as the first, and arrangements should be made to ensure that the late entrants suffer no disadvantage in pay. For vacancies accrued during the War by wastage and permanent expansion, the main source of recruits should be those who have missed their opportunity of competing for the Civil Service because of the interruption, that is, those within normal age limits plus the period of the War. Some of these vacancies should, however, be reserved for those above these limits but not older than thirty. In the administrative class there should be a common field of recruitment up to thirty years of age; in the executive, clerical and sub-clerical classes, one vacancy should be reserved for the older group of candidates for every four allotted to the younger group.

The reconstruction examinations should consist of written examinations in general subjects, plus an interview for the administrative and executive classes. Candidates should be required to possess certain minimum educational qualifications, namely, a university degree of at least second-class honours standard, or a year's continuous full-time university attendance and expectation of such a degree, for the administrative class; full-time education up to seventeen, or higher school certificate for the executive class; full-time education to sixteen or school certificate for the clerical class; full-time education up to fifteen for the sub-clerical class. Temporary Civil Servants should be subject to the same conditions as other candidates, with certain exceptions such as provision for the retention of specially selected senior temporary officers as principal, or analogous executive or departmental grades, or above, who are more than age thirty, and allotment of 15 per cent of the accrued vacancies in the basic executive and clerical grades to the best of the temporary officers in junior grades, above the age of thirty, who have at least two years of service (including any period of service with the Forces).

Established Civil Servants should be eligible for the reconstruction competitions, by which they may obtain promotion to a higher class. Very few of them will be able to comply with the minimum educational qualifications for the executive and administrative reconstruction competitions, and limited competitions should be provided against fixed quotas of vacancies in these classes, so as to restore their pre-war opportunities of sitting for the open competitions. All acting assistant principals promoted since the outbreak of war should be required to succeed in the limited competition before their promotions are confirmed.

Resumption of normal competitions is recommended concurrently with these reconstruction competitions, and candidates coming forward straight from school or university should be required to sit for a normal competition. These are proposed on the same lines as before the War, subject to the introduction of an interview for the executive class, a common examination for clerical assistants, typists and shorthand-typists, and, on an experimental basis, of a system of selection of a limited number of candidates for the administrative class mainly by interview by the Civil Service Commission. This last experiment is to be closely watched and reviewed after, say, ten years. Admission by this method should be confined to those who possess at least a good second-class honours degree.

These proposals, taken as a whole, seem eminently fair, in that they make provision for the entry into the Civil Service of those whose education has been interrupted by direction either to national service or the Fighting Services, and for the retention of those who have proved themselves, as temporary Civil Servants, to be exceptionally suited to their posts. The difficulties likely to arise through the necessity for spreading demobilization over a lengthy period are also foreseen. No guidance is given, however, on the precise methods of selection which are desirable, though no doubt the matter is under consideration; indeed, there is a hint to this effect in the suggestion that a certain number of candidates in normal competitions for the administrative class will be chosen mainly by interview.

The Civil Service Commissioners are facing a difficult task. Selection, in the main, will be by examination; but it does not follow that examinations of the stereotyped form will be adequate. There has been much criticism in the past few years of the methods and the personnel of the Civil Service: in particular, their devotion to precedence and the general lack, and even discouragement of, initiative, have been pilloried. To what extent the type of examination used to select candidates was responsible for the selection or development of this type of mind is difficult to assess, but there can be no question that the British Civil Servant of the future will need, in addition to the virtues which have been envied and admired by the corresponding services of other countries, a whole range of other abilities. As has been said repeatedly in these columns, he must be able to keep in touch with the feeling of the people

at large, he must have initiative, and, particularly in the administrative class, he must be able to interpret not only the letter but also the spirit of policy laid down by the Government. This, of course, raises the whole question of the status of the Civil Servant. The country will require for its administration the best brains available, and the Civil Service will have to attract, and hold, such ability in competition with industry and commerce. It is all to the good that this was so fully recognized in the House of Commons debate on December 14, when the report was warmly welcomed and endorsed.

# THE TREE ROOT AND THE SOIL

## Problems in Tree Nutrition

An Account of Researches concerned primarily with the Mycorrhizal Habit in relation to Forestry and with some Biological Aspects of Soil Fertility. By M. C. Rayner and W. Neilson-Jones. Pp. 184+27 plates. (London: Faber and Faber, Ltd., 1944.) 12*s*. 6*d*. net.

ONE of the most difficult problems, either in botany as a pure science, or in forestry as applied biology, has always been, and still is, to assess the relationships which exist between the root of a tree and its environment in the soil. The reason for this lies, of course, in the fundamental difficulty of observing the root under natural conditions without, at the same time, destroying its environment, or at least changing this in some radical manner. A secondary source of difficulty is also to be found in the need for a specialist's knowledge in making accurate observation of the micro-flora and -fauna of the soil, which form so important a part of the natural environment of the root. The consequence of this is to be seen in the relative neglect in general works on plant ecology of that part of plant associations which occurs below the ground, notwithstanding its admitted very great importance. The book under notice is concerned with the study of a special aspect of this relatively neglected subterranean field. Its topical interest lies herein, and especially in view of the wide interest aroused in the effect of composting on soil fertility—that is, on the value of the soil for root development—by Sir Albert Howard and others during recent years. The book consists of a collection of papers which have appeared at various times since 1934. They are here brought together with little or no alteration or editing and, with a short but excellent introduction, form the chapters of the book. A list of references, a glossary and an index are appended, and there is also a large number of plates illustrating the various papers.

The research work, the accounts of which are here collected together, will be well known to many foresters and botanists. It was begun in connexion with the afforestation of heathland near Wareham in Dorset. Much of this infertile tract of land had proved refractory for the growth of trees, principally pines, which had been sown or planted on it. In many parts growth was so disastrously inadequate that the condition of the trees was obviously pathological and a matter for much concern. Dr. Rayner, who initiated this research, put forward the hypothesis that the cause of this condition lay in the biotic relationships which occurred in the soil rather than in the admittedly low nutrient status as measured chemically; and that these relationships were expressed principally, so far as the trees were concerned, in the type of fungal association made by the root to form true or false mycorrhizas. Proceeding on this hypothesis, composts were prepared from materials such as hop waste and straw, and were added to the infertile Wareham soil. Conifer seedlings raised on such treated soil, whether in the forest or in the greenhouse, made normal vigorous growth and developed true mycorrhizas on their roots. Account had to be taken of the effect on growth of the nutrient salts added with the compost in order to distinguish between the effect of these and the organic matter. It was shown in a series of controlled experiments that the addition of equivalent amounts of nutrient salts by themselves to the heath soil failed to account in any adequate manner for the improvement in growth, both of shoot and root, obtained by composting. It was demonstrated that this improvement was related to the dominance in the soil of fungi such as *Boletus bovinus*, which form normal mycorrhizal associations; to a suppression of the fungi which form false mycorrhizal associations and to a marked increase in the number of short feeding roots. The differences between plants growing on treated and untreated soil and between normal and false mycorrhizas are well shown in the plates.

The biological aspects of soil fertility, in so far as they are illustrated by this work, are discussed in the interesting final paper. It is shown that the infertile heath soil contains a toxic substance, probably hydrogen sulphide, and that treatment which produces healthy growth results in the removal of this. The untreated soil is relatively inactive biotically, fungus activity being strongly depressed. Thus cellulose, such as filter paper, placed in it, shows very little tendency to decay. The reverse is true of soil treated with a suitable compost, in which fungi are very active. The toxic condition is worst in late winter: it is shown that this is correlated with high moisture content and not with low temperature.

This is a valuable and successful piece of work, the results of which are already being put to practical use. Its value is, perhaps, in no way greater than as a demonstration of the need of attempting to obtain a complete and unified view of the biotic association which is, in reality, being exploited in cultivation, and of which the crop plant is only a part, when trying to diagnose the factors responsible for any particular condition of growth. For fertility is the resultant of the interaction of all the factors of this association upon the crop plant. So far as forestry in particular is concerned, this work directs attention to the need for understanding the factors which determine the successful regeneration and maintenance of an adequate root system, especially during the first years after planting and also in the nursery. The rotation required to raise a utilizable forest crop may be lengthened very appreciably by slow unsatisfactory growth during early years. Technical measures for the alleviation of this state of affairs should be based on a knowledge of the adverse factors operating and not merely on guesswork, as has been too often the case in the past. Our knowledge of these matters at present is very slight, and it is highly desirable that further fundamental work should be encouraged. Much of this work will be concerned with the pathological rather than the normal development of plants, and not the least important aspect of the work under

review is the direction it must help to give to future studies of the pathology of the root system.

It remains to discuss the form and purpose of this publication. The book is an undoubted sign of the increasing interest being taken in land cultivation and especially in its scientific foundations. It is a present need of all who cultivate the soil that they shall understand adequately what they are trying to do, from a biological as well as from an economic aspect, for the two are indissolubly related. It is for these people rather than for the biological specialist that this book is, presumably, intended. If so, then it is doubtful whether in its present form it adequately fulfils the needs of the public it is desired to reach. The manner of compilation has resulted in a great deal of duplication of matter, which is rather tiring to the reader and by no means makes for clarity of exposition. The style of writing is also often difficult; this is partly because the papers were written for the instructed biologist with whom neither farmer, forester, nor horticulturalist is necessarily to be classed. No doubt the exigencies of the times made a re-writing of the work completely impossible; but it is to be hoped that at some future time the authors will be able to give a more connected and lucid account of the important relationships which exist between the root, the micro-flora of the soil and their physical environment. In the meantime, those who read through this series of papers will find much of interest and value. The many illustrations and the clear and well set out tables and text-figures are an undoubted help to their reading and understanding.

W. R. DAY.

## ELLIPTIC FUNCTIONS

### Jacobian Elliptic Functions

By Eric Harold Neville. Pp. xv+332. (Oxford: Clarendon Press; London: Oxford University Press, 1944.) 25s. net.

IN the preface to his "Elliptic Functions", written in 1892, Prof. A. G. Greenhill complained that, although the subject was then nearly seventy years old, it had not made its way into the ordinary curriculum of mathematical study in Great Britain. Fifty years later, in a lecture to the London Mathematical Society, Prof. E. H. Neville declared that, while his contemporaries at Cambridge thirty-five years ago would have regarded the elements of the theory of Jacobian elliptic functions as a subject which every undergraduate should study, the time had now come when the subject was largely neglected. He claimed that the study of Jacobian elliptic functions was being killed by the unnatural way in which the functions were introduced, and that every general principle was stifled by the lack of symmetry and the multitude of special formulæ. The book under review is his attempt to restore the Jacobian functions to their proper place in a university curriculum.

An elliptic function is a doubly-periodic meromorphic function of a complex variable $z$. The Argand plane is divided into a lattice of period-parallelograms, and the elliptic functions are functions defined on this lattice. The simplest elliptic functions are of order two; one type is the Weierstrass function $\wp(z)$, with a double pole in each cell; the other comprises the Jacobian functions with two simple poles per cell. While it is the case that $\wp(z)$ is defined directly on the lattice, the modern treatment of the Jacobian functions is not a direct one; the functions are introduced in an artificial way, undoubtedly the best way for the computer, by means of theta functions. In Prof. Neville's book, the Jacobian functions are defined directly by means of the Weierstrass function.

This is not entirely an innovation, but it is coupled with a new notation which exhibits the systematic and organic relations between the functions in a strikingly simple way. Writing $\omega_f, \omega_g, \omega_h$ for the half-periods $\omega_1$, $\omega_2$, $\omega_3$ of Weierstrass, Prof. Neville introduces three primitive elliptic functions defined by

$$\mathrm{pj}\, z = \sqrt{\{\wp(z) - e_p\}} \quad (p = f, g, h)$$

with the condition that the residue at $O$ is unity; then $\mathrm{pj}\, z$ has periods $4\omega_p$, $2\omega_q$, $2\omega_r$, a simple pole at $O$ and a simple zero at $\omega_p$. To complete the notation, he uses a symbol $\omega_j$ to represent the origin, and denotes the function with a simple zero at $\omega_p$, a simple pole at $\omega_q$, by $\mathrm{pq}\, z$. There are twelve functions in the complete set, and they are connected by the simple relations

$$\mathrm{pq}\, z \;\mathrm{qr}\, z = \mathrm{pq}\, \omega_r \;\mathrm{pr}\, z$$
$$\mathrm{pq}\, z \;\mathrm{qp}\, z = \mathrm{pq}'\, \omega_q$$
$$\mathrm{pj}^2 z = \mathrm{qj}^2 z + \mathrm{p}_q^{\,2}$$

where $\mathrm{p}_q$ is the value of $\mathrm{pj}\, \omega_q$.

The Jacobian function $u = \mathrm{sn}\, x$ was originally defined by the elliptic integral

$$x = \int_0^u \frac{du}{\sqrt{\{(1-u^2)(1-k^2u^2)\}}}.$$

To link up the new theory with the old, it is next shown that the relation

$$z = \int_0^w \frac{dw}{\sqrt{\{(g_f^{\,2} - w^2)(g_h^{\,2} - w^2)\}}}$$

is equivalent to $w = -\,\mathrm{jg}\, z$. Comparing these integrals, we see that with $z = x$, the relations are identical if $g_f = 1$, $g_h = -k$, $w = ku$. The actual dimensions and orientation of the lattice on which the primitive functions $\mathrm{pj}\, z$ are defined is immaterial because of their homogeneity in $z$ and the three periods. The condition $g = 1$ picks out of the whole family of similar lattices a special lattice called a Jacobian lattice. If the functions $\mathrm{pq}\, z$ are defined on a Jacobian lattice and are suitably normalized, they are simply the twelve Jacobian elliptic functions; in fact, $\mathrm{fj}\, z$, $\mathrm{gj}\, z$, $\mathrm{hj}\, z$ are the functions $\mathrm{cs}\, u$, $\mathrm{ns}\, u$ and $\mathrm{ds}\, u$ respectively.

Having now reached the customary notation, Prof. Neville again breaks with tradition. Instead of the usual quarter-periods $K$, $iK'$, $K + iK'$, he writes $K_c$, $K_n$ and $-\,K_d$, and uses $K_s$ as a symbol for the origin. This notation is likely to prove valuable, as it simplifies the whole presentation of the theory. For example, in the discussion of the transformations of Landen and Jacobi, the reader sees at once why the transformations work, as well as how.

It remains to complete the link with the definition of $\mathrm{sn}\, u$ by the inversion of an elliptic integral. This part of the book is very well written. It emphasizes clearly the nature of the problem, and gives a solution on entirely new lines.

In this review it has been possible to mention only the salient points of an excellent book. We hope that it will have the success it deserves, and that it will revive interest in this fascinating branch of analysis.

E. T. COPSON.

## The Navigator's Handbook on Modern Compass Adjusting

With particular reference to Wartime Conditions. By John Calder Gillie. Pp. 110. (London: George Allen and Unwin, Ltd., 1943.) 3*s*. 6*d*. net.

MR. GILLIE'S book contains within its small compass all the information necessary for those who wish to understand the factors on which the efficiency of the magnetic compass depends. Among its merits we may refer to its simplicity; it does not require a navigator to understand the nature of the problems. Although it cannot be considered a text-book for examination purposes, it will serve as an introduction to such books. Simple explanations are given regarding the effect of the steel of a ship on the compass, how the disturbing forces are divided into 'co-efficients', the means employed for making the necessary corrections, etc. The principle for degaussing installations—a matter of supreme importance in recent years—is simply explained and also their effect on the compass and the means adopted for overcoming their disturbance. Chapter 9 supplies some simple rules for dealing with compass troubles at sea, and a glossary and index are a useful addition to this highly commendable little book.

M. D.

## Principles of Powder Metallurgy

By Franz Skaupy. Translated by Dr. Marion Lee Taylor. Pp. 80. (New York: Philosophical Library, Inc., 1944.) 3 dollars.

IN view of the extreme interest being taken throughout the industrial world in the production of articles made from sintered metallic powders, a survey of existing knowledge of the fundamental principles involved is very much to be desired. Much of this information has been revealed by research, and the time has come when it should be collected and critically discussed.

Although the book is written by an author who has a considerable amount of original work to his credit, this volume does not, in the reviewer's opinion, perform this function. The general treatment is inadequate in view of the importance of the subject, and the English throughout is so bad that even after careful re-reading there are some sentences the exact meaning of which is still in doubt. It would not, for example, be immediately obvious that by "steam" (p. 20) the author is, in reality, referring to a metallic vapour.

F. C. THOMPSON.

## Science and Progress

By Dr. S. Lilley. (Story of Science Series.) Pp. iv+68. (London: Cobbett Publishing Co., Ltd., 1944.) 2*s*. 6*d*. net.

THIS book is one of a series projected by the Young Communist League. After directing attention to the ways in which science has changed the world's outlook, the author compares the progress of science under various forms of social structure—capitalism, Fascism and in the U.S.S.R. The last chapter deals with science and reconstruction after the War. Throughout the book the importance of organized scientific research is stressed. The author is convinced that this can only be adequately carried out under socialism, and he urges scientific men to fight for the best use of science "as a part of the organised Labour Movement". Half a crown seems a high price for such a propagandist pamphlet.

## The Riddle of Cancer

By Dr. Charles Oberling. Translated by Dr. William H. Woglom. Pp. viii+196. (New Haven, Conn.: Yale University Press; London: Oxford University Press, 1944.) 20*s*. net.

IT is often said, and with some reason, that the education of medical men is so specialized that they are turned out incapable of intelligible literary expression. The average book on a medical subject is seldom read with æsthetic pleasure. In "The Riddle of Cancer" we find the exception. To have presented the problems of cancer research in such a form that the survey is complete, lucid, interesting and not only valuable to the medical profession but also instructive to the inquiring layman, is a task for which the author and his translator deserve the highest praise. If standard medical text-books were only written in such a style, the student's work would be made vastly pleasanter.

The subject-matter covers the most important points in the whole field of experimental cancer research in some detail, and with particular reference to the carcinogenic viruses. A description of the general nature of viruses is included. The author is an exponent of the virus hypothesis, but his presentation of the work in other fields has not been allowed to suffer by his beliefs. There are a comprehensive bibliography and an index.

No doctor or medical student could fail to be edified by this fascinating exposition of a subject which is generally portrayed either luridly and inaccurately for the layman or at sombre, ponderous length for the expert.

## Chemical Industries

Edited by L. Ivanovszky. Nineteenth edition, enlarged and revised. Pp. xxviii+392. (London: Leonard Hill, Ltd., 1944.) 15*s*.

THIS edition of a useful publication has been enlarged in many sections. It includes a large number of detailed tables of physical data, properties of many kinds of materials, glossaries giving definitions of apparatus and products (with many clear diagrams), and ample sections on the most varied aspects of chemical engineering. The work is evidence of great skill in assembling and presenting valuable information in a concise form, and should prove of daily service in technical and other laboratories. The advertising material, which is quite separate from the text and takes up only a reasonable amount of the volume, is also instructive in character and likely to prove very useful.

## A Concise Pharmacology and Therapeutics of the More Important Drugs, together with an Introduction to the Art of Prescribing

By F. G. Hobart and Dr. G. Melton. Second edition. Pp. xvi+168. (London: Leonard Hill, Ltd., 1944.) 12*s*. 6*d*.

THIS is a compact survey of applied pharmacology which can be recommended as a reference book for students in the wards and preparing for examinations. It suffers in places by being so condensed that misinterpretation is possible. The apothecaries system of dosage is used almost exclusively even for drugs, such as those of the arsphenamine series, which are never prescribed in any but metric doses. Proprietary names of some drugs are included, and the examples chosen do not always include the one in commonest use.

# NOMENCLATURE PROBLEMS OF THE APPLIED BIOLOGIST

AT a meeting of the Association of Applied Biologists on November 10 a discussion took place on practical problems of botanical and zoological nomenclature. Dr. J. Ramsbottom (Department of Botany, British Museum (Natural History)), in opening the discussion, referred to the common but erroneous idea that systematists have as their main object the upsetting of established names. Paradoxical though it may seem, changes in scientific names are designed to achieve stability. The principle of priority is that the first validly published name for an organism is the one to be used. This principle is perfectly sound in theory, but its practical application is complicated by the fact that many names published in obscure journals are not rediscovered until years afterwards, when well-known names may have to be rejected in their favour.

The International Rules of Botanical Nomenclature permit of the conserving of well-established generic names under certain conditions; but proposals to conserve specific names have always been defeated in the past and are not likely to be accepted by any International Botanical Congress in the future. The conservation of a specific name would mean fixing the rank and genus of the plant concerned, regardless of subsequent research, which is incompatible with scientific taxonomy. On the other hand, a suggestion emanating from the Royal Horticultural Society to legalize the rejection of certain specified names may contain the germ of an idea which is workable and would achieve the same result in practice. The not unnatural desire of the economic botanist to have one name and one name only for any one plant is likewise incompatible with progress in taxonomy. A plant can have as many names as genera in which it has been placed. Genera may be split up into smaller genera or may be combined into larger genera; or a species may be reduced in rank to that of a variety. Homonyms provide another reason for change: sometimes it is found that the name of a well-known plant has previously been applied to some other species; a change must therefore be made.

To try to fix specific names it has often been proposed that standard lists of conserved names should be prepared. But it should be understood that no standard list can prevent changes of name caused by changes in classification.

Mr. G. R. Bisby (Imperial Mycological Institute) pointed out that mycologists have done little to deal with their special problems of nomenclature; the two articles of the International Rules applying particularly to fungi are still ambiguous and are variously interpreted, and no generic name of a fungus has yet been conserved. He suggested that there should be a permanent executive committee, with changing personnel, for the nomenclature of fungi; that this committee or some other should produce a shorter special code for mycological nomenclature, to apply under the International Rules; that users of names (including plant pathologists and various kinds of mycologists) should be given a chance to vote on proposals, such as the conservation of a few specific epithets, which affect them greatly; that specific epithets of fungi be decapitalized; and that the conservation of generic names be effected when necessary and desirable.

Mr. B. J. Rendle (Forest Products Research Laboratory) gave an account of what has been done in recent years towards stabilizing the names of timber trees. Workers in forestry and wood technology have suffered much inconvenience from changes in the names of common trees, most of them due to the application of the priority rule. Some bodies have found it expedient to fix certain well-known botanical names for their own use, in contravention of the International Rules. The reasons for doing so can be appreciated when it is remembered that trees are often cited by their botanical names in legislation, forest department regulations, contracts for timber concessions, specifications for timber and so on. A measure of stability has been achieved by the Empire Forestry Association and the British Standards Institution in drawing up a list of standard trade names of timbers with their correct botanical names. Over a period of about fifteen years this list has been repeatedly checked and revised, and is now as nearly correct as it can be.

It may not be generally known that the Sixth International Botanical Congress, in 1935, as a practical alternative to conserving specific names, adopted a motion "That an International Committee be appointed to draw up a list of names of economic plants according to the International Rules and that this list may remain in use for a period of ten years". It is understood that the work of this Committee was proceeding very satisfactorily until the outbreak of war; but since then it has been practically impossible to carry on, and much still remains to be done before the list is ready for publication.

Mr. A. Roebuck (Midland Agricultural College, Sutton Bonington) spoke feelingly from the point of view of an advisory agricultural entomologist. He deplored the frequent changes in the names of insects. To the field-worker it is the insect that matters; the name is of importance merely as a label or means of designation, so that one man can understand what another is talking or writing about. He quoted as an example a common insect pest which, in the course of a few years, has been placed in four different genera; much confusion has been caused to farmers in consequence. Genera are sometimes sub-divided on what appear to be insufficient grounds; for example, when three insects are difficult to separate into species, it seems unreasonable to place them in different genera. As a practical suggestion for stabilizing the names of economic insects, Mr. Roebuck advocated the use of English names for British insects, and suggested the preparation of a standard list giving the common names and the corresponding scientific names, the latter to be revised from time to time to keep pace with changes in taxonomic entomology.

Dr. I. Thomas (School of Agriculture, University College of North Wales), while supporting the claim that stability in nomenclature is incompatible with progress in taxonomy, was in favour of a standard list of Latin names of insects for the convenience of economic entomologists, provided that such a list were brought up to date at intervals of ten or twenty years. Periodic revision would provide the opportunity of asking the International Commission on Zoological Nomenclature to suspend the rules in cases where greater confusion than uniformity would result from a change. As an example of the confusion which may be caused by strict application of the law of priority, Dr. Thomas described what has recently happened in the family Aphidæ.

According to Hille Ris Lambers[1] the potato aphis *Macrosiphum solanifolii* (Ashmead, 1882) should now be designated *M. euphorbiæ* (Thomas, 1878). Unfortunately, Theobald stated that the species *solanifolii* Ash. was identical with *gei* (Koch, 1855) and the latter name, as a result of the application by Theobald of the law of priority, became well known in the literature. In all, Ris Lambers gives a list of twenty-four synonyms for this aphis. If it were possible easily to have the rules of nomenclature suspended in this instance, probably all economic entomologists would like to see the name *solanifolii* established. As a result of a discussion on the law of priority the Royal Entomological Society set up a Committee on Generic Nomenclature, but its lists are sometimes not accepted even by the authors of the lists themselves.

Entomological literature is still suffering from the effects of inadequate descriptions of proposed new species. Some of the descriptions given even in present-day literature are totally inadequate. All such work has to be sifted by the bona fide systematist, and it would considerably lighten his labours if something could be done to establish a minimum standard for publications.

Mr. Francis Hemming (secretary to the International Commission on Zoological Nomenclature) described the working of the International Code of Zoological Nomenclature. This was drawn up primarily by workers in systematic zoology in order to meet the needs of workers in that field, and unanimity was only achieved by placing a greater stress on the law of priority than had previously been intended. The International Code won a rapid acceptance among systematic zoologists, but owing to the rigidity of Article 25 (Law of Priority) difficulties were soon encountered, since the application of that Article led to well-known and well-established generic names being replaced by older but less well-known names. Objection was taken to such changes not only by numerous systematic zoologists but also by workers in applied biology, who argued that, whatever rules of nomenclature systematists might adopt for their own purposes, those rules should be such as to secure a reasonable degree of stability for important names widely used in the applied field.

The International Congress tried to meet this criticism at a meeting held at Graz in 1910, in which it was agreed in principle to establish an Official List of Generic Names in Zoology, with their type species. It was hoped that in this way it would be demonstrated that the Berlin Code of 1901 would secure stability for a wide range of important names, and therefore that the area of disagreement would be greatly narrowed. In 1913 at Monaco, the International Congress again considered this problem and decided to settle it by the grant (subject to certain safeguards) of plenary powers to the International Commission on Zoological Nomenclature to suspend the rules as applied to any given case where, in the judgment of the Commission, the strict application of the rules would clearly result in greater confusion than uniformity. It will be seen, therefore, that, as regards zoological names of importance either to workers in the applied field or to workers in systematic zoology, two valuable and important instruments have been placed in the hands of the International Commission in order to assist in the stabilizing of zoological nomenclature.

The International Commission is anxious to extend the Official List so as to include the names of all the most important genera in the animal kingdom. Arrangements are now being made for the early publication of the Official List, giving full bibliographical particulars relating to the names (between six and seven hundred in number) which have so far been admitted. The International Commission is hopeful that the publication of the Official List in this way will demonstrate the value of securing the admission of generic names to the List, and will stimulate specialists in various fields to submit proposals for further additions to the List. Applied biologists can be assured that, where any group of workers notifies the International Commission regarding names which they would like to see stabilized by admission to the Official List, the Commission, for its part, will do everything possible to meet their wishes in this matter. Here and there cases will no doubt arise where it will be found impossible to place some well-known name on the Official List without the Commission first suspending the rules in order to validate that name by suppressing some earlier name, or by fixing as the type of the genus some species other than that which is the type under the International Code. Where there are such cases, the sooner they are brought out into the open and settled once and for all, the better for all concerned.

In the general discussion which followed the more formal contributions, several speakers returned to the suggestion that for certain purposes common names are more convenient and more easily stabilized than scientific names. Standard lists of trade or common names, or more compendious works of reference such as the British Pharmacopœia, must necessarily give the corresponding scientific names in order to fix the identity of the organisms concerned; the scientific nomenclature can be kept up to date by periodic revision without affecting the common names. It was pointed out that although it is impracticable permanently to stabilize scientific names, the risk of confusion can be minimized by following some standard work of reference. It is open to any author of a paper or text-book, for example, to say in his introduction that he is using the names in the *n*th edition of such and such a standard work.

The discussion served to clarify the distinction between name-changes due to advances in taxonomy and those due to conventions such as the law of priority. No responsible body of biologists would seriously propose to limit improvements in classification by permanently stabilizing scientific names, though many would wish to see more careful consideration on the part of taxonomists before upsetting established names by minor changes in the rank of important economic plants and animals. Admittedly, the herbarium worker, dealing with very large numbers of specimens and continually striving towards the ideal system of classification, does not always appreciate the trouble which name-changes may cause to economic botanists concerned with a limited number of species. At the other extreme, the applied biologist, and still more the farmer or timber merchant trying to take an intelligent interest in the scientific aspect of his work, often fails to realize that a name is something more than a label, and condemns the name-changers as being uncompromising, academic and out of touch with realities.

There is a strong case to be made against name-changes which do not signify any progress in taxonomy, as when the resurrection of a prior name invalidates a well-known and old-established name. Botanists and zoologists attending the meeting were able to compare the merits of the international codes of

nomenclature for the two sciences with respect to this problem. The Botanical Rules provide for the conservation of generic names to avoid disadvantageous changes in nomenclature which might result from strict application of the Rules, but they do not permit of conserving specific epithets. Zoologists are perhaps more fortunate in that their standing International Commission on Nomenclature has plenary powers to suspend the rules in cases where their strict application would result in greater confusion than uniformity. Several suggestions were put forward by botanists to restrict changes due to the principle of priority, either by introducing a time limit for the reviving of an old name or by amending the rules so as to allow of the rejection of names which are clearly undesirable. A formal proposal that the Council of the Association of Applied Biologists should examine the question was carried without dissent. B. J. RENDLE.

# GEOCHEMISTRY IN THE U.S.S.R.

By S. I. TOMKEIEFF

King's College, Newcastle upon Tyne

THE term 'geochemistry', like many other scientific terms, has a variable connotation. If geochemistry means simply the chemical study of the earth or parts of the earth, then geochemistry must be as old as chemistry itself, and dates from the attempts of Babylonian and Egyptian metal-workers and potters to understand the nature and properties of their materials. If, on the other hand, geochemistry is not only that, but something more, namely, an attempt to understand the distribution of chemical elements in the different parts of the earth, the migration of chemical elements and the laws of their combinations in the process of mineral formation, then geochemistry is indeed a young science. This is why the Russian geochemists claim that geochemistry is the science of the twentieth century. In saying that, they imply that science does not consist of a mere collection of data, but involves also theories and hypotheses which link up the data to form an organized whole; that a real science involves a definite mental technique in handling problems, setting up new points of view, and, in general, marshalling the results of experience. According to the Russian men of science, geochemistry is now passing from the stage of the 'data of geochemistry' to the 'science of geochemistry'; and from being a mere handmaid of mineralogy, petrology and economic geology, it is emerging as an autonomous science with its own problems, scope and methods.

A determined attempt to establish an autonomous science of geochemistry was made by Vernadsky, Fersman, Goldschmidt and Niggli, to mention only the four most prominent workers in this field. It is in Russia that geochemistry has taken deepest root, no doubt because of the widespread search for economic minerals and the scientific renaissance during the last two decades. Unfortunately, the intellectual isolation of the U.S.S.R. and the language barrier has made it difficult for scientific workers in other countries to become really acquainted with this movement.

The old descriptive mineralogy and descriptive petrology, which made such great strides during the last century, were predominantly static sciences. Many attempts at a genetic approach were made before Vernadsky, but perhaps it is to him that we owe its most forcible expression. He began in 1890 to break new ground in his lectures at the University of Moscow, and developed this work in his book on descriptive mineralogy[1], which began to appear in parts in 1908 and is still unfinished; for the surge of new ideas in the mind of the author led him to embark in 1925 on yet another serial work, the history of minerals[2]. Unfortunately, these books are not only left unfinished, but also their subject-matter is presented in such an inchoate form that they are difficult to follow. However, the author has managed to present his ideas more coherently and in application to more restricted problems in a book published in Russian, German and French[3]. In it we see a definite attempt to build a new geochemistry on the basis of the old mineralogy—an attempt full of daring ideas and schemes. It is a book that may shock an orthodox mineralogist and leave him bewildered and dazed. In spite of this, however, the book is very vivid and stimulating, and it suggests many new problems which, if followed up, may lead to some new fields of science. Vernadsky's next book is even more daring, for it deals with that still more complex realm, the biosphere, the sphere of life, full of complexities and change. By publishing this book, Vernadsky stimulated the study of what he called 'biogeochemistry'—the study of the chemical composition of the living matter in relation to the organically formed rocks. A biogeochemical laboratory was established in the U.S.S.R. and it soon became the thriving centre of a new research school

Vernadsky's younger contemporary, Fersman, began his lectures on geochemistry in Moscow's People's University in 1912. By that time he had already conceived the idea of a book which would not only include all the data of geochemistry, but also present a synoptic view of the whole subject. It is important to note here that Fersman, like Vernadsky, being a first-class mineralogist, made the approach to geochemistry from the side of mineralogy. His main interest at that time was concentrated on regional mineralogy, or as he called it 'topomineralogy', and in 1922 he published the first part of his ambitious work on the geochemistry of Russia[5], which was left unfinished under the stress of the new ideas which emerged from it. In this book he used regional mineralogy only as a basis for a superstructure of geochemistry. His mineral assemblages became genetic types, mineral provinces became geochemical provinces, and these in their turn were incorporated into geospheres, the whole being linked up into unending genetic cycles. In this way genetic mineralogy and genetic petrology became incorporated into the all-embracing geochemistry. Not satisfied with geospheres and the unknown centrosphere, Fersman overflowed into the cosmos, incorporating the sun, the stars and the meteorites, merging geochemistry into cosmochemistry. These ideas were fully developed by him in his next book, published in 1923[6].

Not only interested in the distribution of the chemical elements in the geospheres and in the cosmos, Fersman made an attempt to find the causes of such a distribution. Following up the guiding ideas of De Launay and Goldschmidt, he tried to connect up the distribution of the chemical elements and their atomic structure, first in a series of papers and later in a monumental work of more than 1,500 pages entitled "Geochemistry"[7]. The main body of this work is contained in the first three volumes; the

fourth volume provides reference tables and geochemical data for all the chemical elements. A fifth volume, which was announced, was replaced by a separate publication dealing with applied geochemistry[8].

Already in 1922 Fersman emphasized that the main purpose of geochemistry is not merely the chemical study of minerals and rocks, but also the study of the distribution and migration of chemical elements in the earth. In his book on geochemistry, Fersman defines the aim and the scope of this science even more precisely. "The purpose of geochemistry is the study of the element-atom in the conditions prevailing in the earth's crust (as well as in the parts of the cosmos accessible to our exact observations). Geochemistry studies: (*a*) the quantitative distribution of the chemical elements in the earth's crust and their dispersion and local concentration; (*b*) the combinations of different elements in the different parts of the earth's crust and their distribution in space and time under the influence of different chemical processes; (*c*) the migration of elements and the laws of such migration as determined by the different thermodynamic conditions of their environment; and (*d*) the behaviour of chemical elements either in the environment of the earth's crust or as compounds and particularly as crystals. This may be expressed even more simply: geochemistry studies the history of chemical elements in the earth's crust and their behaviour under different thermodynamic and physico-chemical natural conditions".

Taking the dictum of Lomonosov—"From observation follows theory, theory corrects observation"—as his motto, Fersman packs his book with data culled from all possible sources, and gives an imposing list of references to the literature in all languages. The observational or experimental data is used by him for the construction of far-reaching theories, or, as some may say, hypotheses. A host of new and daring ideas spring into existence and enmesh his array of facts. These new ideas often necessitate the invention of new terms, and an ordinary mineralogist or chemist may be greatly puzzled meeting terms such as *EK*, *VEK*, clarke, paragene, co-centre eutectite, orthotectite, etc. Here is the explanation of some of his key-terms: clarke (in honour of F. W. Clarke, the author of "The Data of Geochemistry") is the average quantity of a given element in any geochemical system; *EK* (energy coefficient) is an index expressed in calories per gram-mol at 0° Abs., showing the amount of energy contributed to a heteropolar compound by the transfer of an ion from infinity to its present position in the crystalline lattice; *EK*'s are calculated from the energy of the crystal lattice, but an approximate formula gives $EK = Kw^2/2R$, in which $K$ is a coefficient (almost equal to unity for anions), $w$ is valency, $R$ is ionic radius; *VEK* is *EK* divided by valency, or the energy per valency of an ion; paragene is a complex and as yet undetermined function depending on the crystal chemical constants and energy coefficients. It is suggested that the paragene, when properly determined, may fix the relative position of a compound (mineral) in the paragenetic succession.

The field covered by geochemistry as outlined by Fersman is most extensive. It includes all systematic mineralogy and petrology, the study of ore deposits, crystal-chemistry and physical chemistry as applied to natural processes. All these sciences are combined into a unified scheme following definite leading ideas. In his book on geochemistry, Fersman begins with the consideration of chemical elements and then passes to crystals, geospheres, migration of chemical elements, clarkes, geochemical processes and geochemical types. At a later stage a detailed examination of the periodic system is undertaken in the light of atomic structure and crystal-chemistry, and also a detailed treatment of energetics as applied to geochemistry, including the energy of the crystal lattice, energy coefficients (*EK* and *VEK*) and the principle of the paragene. Fersman's main idea is that the energy coefficients of ions provide the fundamental ground for the understanding of all geochemical processes: "The course of a natural process and the association of minerals and elements in space and time are determined by the law of the decrease of the space-lattice energy. The application of *EK*'s, for example, the energy of simple and complex ions forming the lattice, provides an important key for the solution of geochemical problems from the point of view of energetics".

This application of 'geoenergetic analysis' to all geochemical problems is most clearly marked in his treatment of pegmatites—coarse-grained rocks crystallized out of a water-rich rest magma during the later stages of magmatic consolidation. Fersman has been engaged in the study of pegmatites during the last thirty years, and has published a number of papers on this subject. In 1931 he published a large book on granite-pegmatites, a third, revised and enlarged edition of which appeared in 1940[9]. This is to be followed by another work dealing with syenite-pegmatites. The book on granite-pegmatites is packed with data culled from all parts of the world, including many new observations on pegmatites in the U.S.S.R. The factual data are interpreted according to a definite genetic scheme, and all types of pegmatites are considered as members of a continuous series corresponding to the stages of the cooling of granitic magma. The chronological sequence of these stages is as follows: (1) magmatic (900°–800° C.), (2) epimagmatic (800°–600°), (3) pneumatolytic (600°–400°), (4) hydrothermal (400°–50°), (5) hypogenic (50°–0°). Each stage is characterized by a more or less definite mineral assemblage in a given type of pegmatite. The main concern of Fersman is to find the cause or causes of this association and succession of minerals (paragenesis). A suggestion is made by him that minerals with a high lattice-energy crystallize out first, but this is complicated by other factors, such as the composition of the melt, the amount of volatiles, the nature of the ions present and many others. The book on granite-pegmatites is definitely a work on the geochemistry of these rocks, and it provides a test piece for his geochemical theories as applied to magmatic rocks. At the same time, a systematic description of pegmatites of the U.S.S.R. has been undertaken in a series of monographs, two of them already published[10]. Pegmatites contain a number of economically valuable minerals and such a survey is of great practical importance.

The new school of geochemistry has made and is making rapid progress in the U.S.S.R. It was fostered by the formation in 1931 of the Institute of Geochemistry, a research institute forming part of the Lomonosov Institute at the Academy of Sciences. The Lomonosov Institute (named in honour of the great Russian scientist, M. V. Lomonosov, 1711–65), occupies a large new building in Moscow and houses a great number of research workers, many of them

engaged on problems of economic importance. As an example of such work one may mention a recent publication on the geochemistry of gold by Zviaginzev[11]. In this book the author gives an account of the distribution and migration of gold in geospheres, and traces the history of gold from its concentration in hydrothermal veins to its renewed concentration in placers. Several interesting problems are discussed, such, for example, as the occurrence of gold in meteorites, in water, in plants and in coal. The concentration of gold in the hands of man (anthroposphere) is estimated to be of the order of 0·001 per cent of the total amount in the earth.

It is difficult to avoid the impression that geochemistry in the U.S.S.R. tends to the fanciful, and the criticism so implied is not altogether unjustified. It must, however, be noted that Russian geochemists have done and are doing much spadework, and that ideas and theories, which may have seemed extravagant, have proved valuable both in the co-ordination of knowledge already acquired and in the search for knowledge as yet unrevealed. In this branch of science, as in others, progress depends on daring thrusts into the unknown, on the blazing of new trails which must later be consolidated by patient experimental and observational work.

## CRYSTAL DYNAMICS

THE subject of crystal dynamics, which is concerned with the vibrational movement of atoms in the solid state, is now of respectable antiquity. The classic papers are perhaps those of Einstein[1], Debye[2] and Born and v. Kármán[3], which deduce the specific heat of metals from the vibrational energy of the crystal lattice. The whole subject has recently received a new interest and stimulus by the discovery that the thermal vibrations of the atoms of a crystal produce measurable effects in the background of X-ray diffraction patterns. The normal Bragg-Laue diffraction pattern of a crystal is characteristic of its geometry: the thermal motion of the atoms appears as a pattern in the background of the diffraction photographs. This is a subject which evidently has wide ramifications, and in fact must ultimately affect every branch of physics concerned with the solid state of matter. The experimental and theoretical development of the subject have been ably summarized by Lonsdale[4] and Born[5].

That ideas concerning the vibrations of so complex a system as a crystal lattice should depend to some extent on the mode of approach to the problem is perhaps to be expected, but the extent to which they diverge is surprising. Sir C. V. Raman approaches the matter, naturally, by a road leading from the optical characteristics of transparent crystals: such phenomena as the Raman effect, luminescence and absorption spectra should throw light on the nature of vibrations in the crystal lattice. Recently there has appeared "A Symposium of Papers on the Dynamics of Crystal Lattices"[6], in which Raman develops his ideas about the atomic vibrations in a crystal, while his collaborators extend his ideas in several directions.

The basic fact which the theory seeks to explain is that the Raman spectra and luminescent spectra of crystals consist of a number of discrete monochromatic lines. That these lines are superimposed on a continuous background of intensity is ignored. To provide an explanation for the discrete lines in the spectra Raman seeks to endow the crystal lattice with a limited number of discrete modes of vibration. The absorption of energy from the incident beam by one of these modes would give an absorption line, while the communication of energy from one of the modes would give an emission line in the emission spectrum.

Raman's argument seems to run as follows. Directing our attention to a particular atom in a particular crystal cell, we see that the restoring force which operates when it is displaced from its position of equilibrium is the same as that which acts on any crystallographically equivalent atom in any other cell of the crystal, because all these equivalent atoms have the same kind of neighbours arranged in the same pattern. This identity of the force constants suggests that the displacements of equivalent atoms in a normal mode of vibration are related in a simple way. Raman is then led to the result that equivalent atoms in the crystal have all the same amplitude of vibration, their phases being either the same or opposite in neighbouring cells along the three crystal axes. This means that the atomic vibrations repeat themselves in a space pattern of which the unit has twice the linear dimensions, and therefore eight times the volume, of the unit cell of the crystal lattice. If there are $p$ atoms in the unit cell of the crystal, there are $8p$ atoms in the superlattice cell into which the vibrations divide the lattice. Each of these $8p$ atoms has three degrees of freedom, so the total number of normal modes is $24p$, three of which correspond to translations of the crystal as a whole and do not rank as modes of vibration of the lattice. The total number of frequencies so enumerated will also be reduced by the symmetry of the crystal structure.

The foregoing argument thus leads to the result that the vibrational spectrum of the crystal consists of a small number of discrete (monochromatic) frequencies. The result is founded on an arbitrary assumption and is quite at variance with all other work on the subject. Raman concludes his paper with some (unfortunate) remarks about Born's "postulate of the cyclic lattice", an idea which both Born and Lederman[7] have re-examined and found to be justifiable.

The remainder of the symposium consists, on the theoretical side, of four papers by E. V. Chelam on the enumeration of the normal modes of vibration of several types of cubic lattice, and two papers by G. N. Ramachandran on the vibrations of the fourteen Bravais lattices. The experimental background, which the theory is designed to explain, is reviewed by R. S. Krishnan, who deals with the Raman effect in crystals, and by D. O. Pant, who surveys the experimental data concerning the luminescent spectra of crystals. It is unfortunate that these

authors and their eminent leader have not given their careful attention to the X-ray evidence which has been so well described by Dr. Kathleen Lonsdale. This demands a nearly continuous spectrum of vibrational frequencies in the crystal quite contrary to Raman's theory. Krishnan, moreover, ignores the continuous background to the Raman spectrum of sodium chloride observed by Fermi and Rasetti[8] and stresses only the lines which are superimposed on the background. The lattice theory developed by Born (*loc. cit.*, p. 309) provides an explanation of the X-ray results and also of the small number of lines in the Raman and absorption spectra of crystals. There does not, therefore, seem to be any necessity for introducing arbitrary assumptions into the dynamical theory in order to reduce the number of normal modes of vibration to a few discrete frequencies. # OBITUARIES

## Sir Joseph Arkwright, F.R.S.

JOSEPH ARTHUR ARKWRIGHT, an honorary member of the staff of the Lister Institute of Preventive Medicine and a former member of the Medical Research Council and of the Agricultural Research Council, died on November 22 after a short illness, a few weeks after the death of his friend and colleague, Sir John Ledingham. He was the son of the late Arthur William Arkwright, of Broughton Astley, Leicestershire, and was born on March 22, 1864. He was educated at Wellington College, and Trinity College, Cambridge, and pursued his medical studies at St. Bartholomew's Hospital, London, qualifying in 1889 and graduating M.D. in 1895.

Arkwright had a many-sided and distinguished career. After postgraduate work at St. Bartholomew's, the Victoria Hospital for Children, Chelsea, and the West London Hospital, he engaged for some years in general practice, chiefly at Hales Owen, Worcestershire; but in 1905 he renounced this work to join the staff of the Lister Institute, first as a voluntary research worker and from 1909 onwards as assistant bacteriologist. He retired from active duty in 1927, but continued to work at Chelsea as an honorary member of the staff. He was elected a member of the governing body of the Institute in 1932 as the representative of the Royal Society and served until January 1 of this year, when the Board recorded its high appreciation of the value of his wise counsel during the period of his service.

Arkwright's work at Chelsea was interrupted by the War of 1914–18 when, after investigating an epidemic of cerebro-spinal meningitis among troops encamped on Salisbury Plain in 1915 and recording his observations on the grouping of meningococcus strains that were isolated, he served in the R.A.M.C. with the rank of major as pathologist at St. George's Hospital, Malta, where with Dr. E. A. Lepper he investigated the occurrence of blackwater fever in the Eastern Mediterranean area. In 1918 he was appointed a member of the War Office Committee on Trench Fever, and with his colleagues, Bacot and Duncan, demonstrated the constant association of the virus of trench fever with *Rickettsia quintana* in lice. In 1922 he accompanied Bacot to Egypt at the request of the Egyptian Government, to investigate the etiology of typhus fever. After two months work in Cairo, both contracted the disease, to which Bacot unfortunately succumbed; Arkwright recovered from a severe and hazardous illness. Previously, in 1920, he had carried out a series of investigations on foot-and-mouth disease under the auspices of a committee appointed by the Ministry of Agriculture and Fisheries and later became chairman of this committee, as also of the Agricultural Research Council's *Brucella abortus* Committee and the joint committee with the Medical Research Council on tuberculosis.

The subject, however, with which Arkwright's name will always be associated is that of bacterial variation, and his fundamental and luminous researches on the forms of bacteria that he named the "S" and "R" variants, embodied in an outstanding communication to the *Journal of Pathology and Bacteriology* in 1921, gave a new impetus to research in this direction. He was also deeply interested in the carrier problem, and his book, "The Carrier Problem in Disease", published in collaboration with the late Sir John Ledingham, was an important contribution to this subject. He also contributed freely to the Medical Research Council's "System of Bacteriology" and to numerous scientific journals.

Arkwright's active and versatile mind found many channels for its expression. He was appointed a member of the Medical Research Council in 1930 and of the Agricultural Research Council on its inception in 1931. His public-spirited and useful work in these directions only terminated in 1940, when in his seventy-sixth year he retired from the latter of these offices. He was made a fellow of the Royal College of Physicians in 1916 and served on the Council during 1929–31. He was elected a fellow of the Royal Society in 1926, and the honour of knighthood was bestowed on him in 1937 for his outstanding scientific achievements.

Arkwright had a charming personality and extended an ever-helping hand to the younger workers at the Lister Institute, to whom he was a source of encouragement and inspiration. Apart from his special studies he had a broad cultural and scientific background and was a field naturalist of no mean ability, possessing an exceptional knowledge of field botany and of horticulture, and a good working knowledge of other branches of natural science. He married in 1893 Ruth, daughter of the late Joseph W. Wilson, who, with their three daughters, survives him. R. ST. JOHN-BROOKS.

## Dr. G. A. Tomlinson

WE regret to record the death of Dr. George Arthur Tomlinson, a principal scientific officer at the National Physical Laboratory, on December 1, after a short illness.

Tomlinson was born on January 7, 1885, and educated at Nottingham High School, passing on to University College, Nottingham, where he took the degree of B.Sc. (London) in engineering, with first-class honours. He then spent two years as a research student at St. John's College, Cambridge, on post-graduate research. He also gained honours in electrical engineering in the City and Guilds (London) exam-

ination. On leaving Cambridge he worked for a time with Messrs. Kelvin and James White, of Glasgow, on researches relating to electrical and magnetic problems. Later he held, in turn, lectureships in electrical engineering at the Rutherford Technical College, Newcastle-on-Tyne, and at the Borough Polytechnic, London.

In 1915 Tomlinson was appointed to a post at the National Physical Laboratory, where he was first engaged, during the War of 1914–18, on the verification of gauges. From this he turned his attention to devising apparatus for the measurement of gears and gear-cutting hobs, then almost a new field, with which he continued to be closely associated for the rest of his life, developing further methods and instruments for checking the accuracy of gears of all sizes, and of the hobbing machines used in their production. In this subject he became a recognized expert whose advice was sought both by government departments and by private firms.

Among other matters Tomlinson also devoted himself successfully to the study of molecular cohesion in relation to surface phenomena such as pressure corrosion and friction. Following this, he became interested in the geometrical properties of surfaces, and devised the now well-known surface-finish recorder which bears his name, and which is an excellent example of his direct attack on a problem, and his faculty for attaining results by the simplest means.

An altogether different line of work was in connexion with the improvement of time-keepers. He spent much time on the development of a new type of vibration clock, and in experiments on new methods for driving free pendulum clocks. Incidentally to this work, he designed a new type of chronograph for the comparison of time-signals to an accuracy of 0·1 millisecond.

Tomlinson had a flair for instrument design which amounted to genius. More often than not he would make the first model of a new instrument with his own hands, using the material nearest to hand. But though these first models might have a somewhat gimcrack appearance they were always usable tools and, being usually designed to meet some immediate need, were often put into practical service for considerable periods before, as happened in many cases, their proved utility made it desirable to re-design them in a form suitable for commercial production.

Tomlinson—"Tommy" to his friends—had a charming and lovable personality. Modest and unassuming, he was always ready with advice and help for others, and a source of inspiration to those who worked with him. He was a rare combination of man of science and practical engineer, and his death is a national loss. He leaves a widow and two sons.

J. E. SEARS.

## Dr. J. N. Sugden

DR. JAMES N. SUGDEN, senior lecturer in inorganic chemistry in the Imperial College of Science and Technology, who was killed by a flying bomb on July 11, 1944, was born at Silsden, near Keighley, on March 27, 1894. As a pupil of the Trade and Grammar School, Keighley, he came under the influence of a former student of chemistry in the Royal College of Science, Mr. Harry Harper, and after a period of study at the Technical College, Huddersfield, he proceeded to South Kensington in 1913.

Having graduated as an associate with first-class honours, and having been awarded the Neil Arnott Studentship and a Royal Scholarship, Sugden devoted himself to investigations which naturally soon became closely related to war problems. He received a commission in the Army, and under the direction of the late Prof. H. Brereton Baker he took part in some of the early scientific work which arose out of the enemy's use of poison gas. Later he was much concerned with the technical development of methods and equipment for ensuring an adequate supply of safe drinking water for troops dependent on contaminated supplies, particularly in France and in Mesopotamia. Under his immediate supervision, large mobile and static chlorination plants with their control laboratories were designed, tested, dispatched, and operated. Returning in 1919 from a prolonged visit to Iraq, he was appointed a demonstrator in chemistry at the Royal College of Science (Imperial College of Science and Technology); he was promoted to be a lecturer in 1922, and senior lecturer in 1943. There he quickly established a reputation as a most conscientious and efficient teacher.

Sugden's methods were often ingenious, and sometimes unorthodox; for he was an individualist whose acidulated epigrams were a tonic to the laggard, but whose meticulous care and patient instruction were an inspiration to every diligent student. Prolonged ill-health restricted the scope of his physical activity, but his mind seemed the more acute. His principal contribution to chemical knowledge concerned the hydration of salts in aqueous solution. This study yielded most interesting results; but he placed his teaching duties before all other attractions, and never regained the physical strength to pursue the inquiry.

Sugden was not an easy man to know. His bachelor life was lonely, and his friends, deliberately few, scattered by the march of time. He was interested in British silver coins, and liked to try his hand at the more erudite literary competitions in periodicals, especially those involving a foreign language. He was a judge of burgundy, and his efforts as an amateur photographer disclosed an artistic perception. While few could phrase a rebuke more mordantly, few enjoyed more gloomily the humour of life or more often delighted their acquaintances with gleanings among the unusual, the comic, or the profound. By his colleagues, as well as by many of the students to whom he ministered for twenty-five years, he will be remembered with affection and with the respect due to one who, having well considered, possessed the courage of his convictions.

A. A. ELDRIDGE.

## Prof. B. B. Ray

PROF. B. B. RAY, Khaira professor of physics in the University of Calcutta, died on July 29, 1944. He was a fellow of the National Institute of Sciences of India; and presided over the Physics Section of the twenty-ninth session of the Indian Science Congress, held at Baroda in 1942. Prof. Ray joined the University of Calcutta in 1921 as a lecturer in physics and was one of the early batch of students who carried out research work in physics under Sir C. V. Raman.

Prof. Ray visited Europe twice, once in 1923 and again in 1935. During his first visit he worked at Uppsala in the laboratory of Prof. M. Siegbahn and at Copenhagen under Prof. Niels Bohr. It was in Prof. Siegbahn's laboratory that Prof. Ray learned

the technique of research on X-ray spectra. On his return to India he devoted himself to founding an active school of research on X-rays.

In 1935, he was elected to the Khaira chair of physics in the University of Calcutta.

Immediately before his death, Prof. Ray was carrying out researches on the absorption and emission spectra in the soft X-ray region. He was also conducting investigations on the luminescence of solids under X-ray bombardment. Prof. Ray had a charming and lovable personality and was very popular with his students. Science in India has suffered a great loss by his untimely death at the early age of fifty.

WE regret to announce the following deaths:

Prof. Edward F. Berry, professor of civil engineering at Syracuse University, on August 28, aged fifty-four.

Prof. E. F. Gaines, professor of genetics in agronomy and cerealist in the Agricultural Experiment Station of the State College of Washington, known for his work on the inheritance of disease resistance in cereals, on August 17, aged fifty-eight.

Dr. Walter L. Jennings, formerly professor of chemistry and later director of the Worcester Polytechnic Institute, Massachusetts, on September 2, aged seventy-seven.

# NEWS and VIEWS

## Royal Institute of International Affairs

THE annual report of the Council of the Royal Institute of International Affairs for the year ended June 30, 1944, gives a brief review of the growth of the work since the Institute was established in 1919 for the scientific study of international affairs. A committee was appointed by the Council on April 19, 1944, to review the developments of a quarter of a century, "to re-examine the purposes for which the Institute was founded; to inquire whether any change is desirable in the present activities of Chatham House, or any shift of emphasis in order to increase its influence and value". Researches into international problems published during these twenty-five years appearing in the growing list of volumes under the auspices of the Institute have already placed Chatham House on a footing comparable with the national institutions established in other fields. Strict adherence to the basic rule that the Institute should express no corporate opinion on any aspect of international affairs has contributed in no small measure to recognition of its integrity and to the attainment of its present position. Means of study have been provided for the serious student of international affairs. The Library is the most comprehensive collection of its kind in England, and has overflowed from its cramped quarters into more ample reading rooms. The Press archives are unique, and after the War, when these archives are returned to Chatham House by the Foreign Office Research Department and again become generally available, they will be a source of information that will attract scholars from all over the world.

With regard to the past year, the report refers to the opening on May 17, 1944, of the additional premises at 9 St. James's Square, London, the re-publication in January 1944 of *International Affairs* as a quarterly, by arranging for printing in Canada, and the opening in New York on February 1 of a Publications Office for distribution of the Institute's publications, and to the continuance of week-end courses on international affairs for officers and men of the Forces. A list of the fourteen courses arranged is appended, and the 300 available places at each were allocated among the Royal Navy, the British Army, Royal Air Force, Canadian Army and U.S. Army. The "British Year-Book of International Law", which was suspended at the outbreak of war, is to re-appear shortly as a Chatham House publication covering the period 1940–43. Reconstruction studies have continued, but only one report, "The International Secretariat of the Future", was published during the year. A preliminary report of the group dealing with economic and social problems will be published shortly under the title "The Economic Lessons of the Nineteen-Thirties", as well as a series of pamphlets under the title "Looking Forward" to assist members of the general public to form their opinions on some of the principal international problems of reconstruction. One of these, by Dr. C. H. Desch, deals with "Science and the Social Order". Lists of individual studies published during the year, in the press or in progress are included; with notes on Far Eastern studies and the Institute of Pacific Relations, British Commonwealth relations, Allied research in London and on the work of the branches and of the institutes in the Dominions and in India.

## Town and Country Planning in Britain

BULLETIN No. 4 of the Tory Reform Committee deals with "Government Policy for the Rebuilding of Urban Areas" as set forth in the Town and Country Planning Act, of which it gives a concise exposition. Development in Great Britain has hitherto been haphazard, uneconomical and unplanned for five reasons. The planning authorities have always been too small and there has been no central machinery co-ordinating local schemes in accordance with a national policy. Any planning authority inclined to take a less parochial view met financial difficulties resulting from its small size. Urban authorities were similarly penalized if they sought to make an enlightened dispersal of their population, because this meant handing rateable value to neighbouring authorities. Again, just where dispersal was most needed, land values rose sharply in proportion to the need for using the land. Compulsory acquisition by an authority was made slow, difficult and costly by the old piecemeal procedure.

The Tory Reform Committee holds that there can be no doubt that the elimination of all local inquiries, except in special cases, as was recommended by the Uthwatt Committee, would greatly expedite the compulsory acquisition of land, but it would be impossible to justify the compulsory purchase of the property of individuals without giving them an adequate opportunity of stating their objections. Again, it would be disastrous if post-war planning resulted merely in a tidier expansion of the existing industrial aggregations. What is really required is, first, the encouragement of industry into

dustrial areas which are menaced with post-war unemployment, and when this need has been met, the dispersal of industry and populations into communities ten or fifteen miles outside existing towns, as contemplated, for example, in the Plymouth plan. The provisions of the Act, as in all legislation dealing with the ownership of land, are complicated and difficult, but the Committee believes it offers a more acceptable solution of the problems incidental to the public acquisition of land than has been proposed in various plans put forward since planning seized the public imagination.

## Universities of Britain and the Future

A SPECIAL number of the *Political Quarterly* devoted to the future of the universities of Britain contains an article by Sir Lawrence Bragg, "Organisation and Finance of Science in Universities". Sir Lawrence urges the importance of further steps to ensure that the fullest use is made of scientific men and potential scientific workers of the highest quality; and he suggests that more care should be taken to see that the highest ability does not 'fall off the educational ladder' before reaching the university, and that young people possessing such qualities should be carefully guided as to the courses they pursue at the university and the careers they take up afterwards. Then he suggests that an attempt should be made to avoid distracting our best university men from their real work by loading upon them too many extraneous duties, and finally he directs attention to the way in which lack of sufficient money for aids to research reduces the efficiency of our best scientific investigators. Dr. C. P. Snow also examines the question of careers, and pleads for a standing Government committee to report at least once a year on trends in employment of graduates; the Appointments Department of the Ministry of Labour should act in close touch with such a standing committee and have as an essential task the diffusion of information to undergraduates; and the university appointments boards should be strengthened in the large universities on the Cambridge scale, and developed on tutorial lines in the smaller universities. Sir Ernest Simon discusses the number of university students, and Mr. G. D. H. Cole's article on "The Social Studies in the Universities" includes a suggestion for group research in place of individual research for the average postgraduate student, which may have potentialities elsewhere also. Bruce Truscot discusses the "University and its Region", indicating possible developments, and Prof. John Macmurray the functions of a university, stressing the importance of the cultural function, in which the universities of Great Britain are most conspicuously lacking.

## Research and Development in Scotland

SOME further notes on "Scientific Research in Scotland" are contributed by Mr. R. H. S. Robertson to *Discovery* of October, to some extent amplifying those in Bulletin No. 3 of the Scottish Reconstruction Committee (see *Nature*, August 12, p. 205). Some reference is made to the research stations already established in Scotland such as the Macaulay Institute, the Rowett Institute and the Fisheries Research Station at Torry, but no fresh evidence is advanced in favour of the formation of a new Scottish research station or branch of the Department of Scientific and Industrial Research. What is required is rather more attention to local conditions and problems and more effective liaison with the research boards and stations of the Department, whether they are located in Scotland or elsewhere. Modification or adaptation of the Portal house may be as important to suit conditions in Devon or Cornwall as to suit those in Scotland. To duplicate the work of the Building Research Station when the first need is a large all-round expansion of research would be both wasteful and inefficient. The national research stations, wherever located, should be strengthened so as to be capable of dealing with the development of national resources, whether they are found in Cornwall or Durham, Glamorgan or Buchan. In regard to the location of industry, Mr. Robertson is on firmer ground, and his paper emphasizes the need for action on the lines of the Barlow Report and as foreshadowed in the White Paper on "Employment Policy".

## Early Medical Books at Glasgow

To illustrate a current series of lectures on "The Evolution of Social Medicine", by Dr. Douglas Guthrie, there have been placed on view in the Hunterian Library of the University of Glasgow some interesting works from the Hunterian and the Ferguson Collections, and from the library of the Royal Faculty of Physicians and Surgeons. Dr. William Hunter, eminent in London as an obstetrician and an anatomist, though not so famous as his younger brother John, bequeathed his library and museum to the University of Glasgow, where it forms a rich mine of learning. Besides his own magnificent atlas, "The Anatomy of the Gravid Uterus" (1774), the books selected from Hunter's library include some of the earliest works on midwifery. Among the medical classics in the exhibition are the first edition of the works of Hippocrates, printed in Greek by Aldus of Venice in 1526, and another Aldine work, Celsus' "De Medicina", the oldest medical document after Hippocrates, of which the 1528 edition is shown, the Florentine edition of 1478 being still stored away for safety. From the Ferguson Collection come two of the finest works of Paracelsus, "Grosse Wundarztney", 1536, and "Paramirum" (1565), next to which may be seen David Laing's copy of one of the rarest of medical books, Michael Scot's "Liber phisionomie" (1477). Herbal literature is represented by "De historia stirpium" (1540), by Leonard Fuchs, Nehemiah Grew's "Anatomy of Plants" (1682), with many beautiful drawings, and the magnificent "Curious Herbal" of Elizabeth Blackwell (1737). Another rare work is "An Account of the Foxglove" (1785), in which William Withering of Birmingham, a friend of Erasmus Darwin, introduced the use of digitalis in heart disease, having learned of its use as a 'folk remedy' from his country patients. Although the valuable University manuscripts have been stored away for safety, it has been possible to show from the Faculty library a volume of letters of advice, or "consilia", written and signed by Herman Boerhaave of Leyden (1668–1738); the earliest minute book of Glasgow Medical Society (1815), and a manuscript diary of the Crimean War, written by George Buchanan, the first professor of clinical surgery at the University of Glasgow. The exhibition, which has been arranged with the co-operation of Dr. W. R. Cunningham, University librarian, and Dr. Snodgrass, librarian of the Royal Faculty of Physicians and Surgeons, will remain open until the end of January.

## Sunspots and Associated Phenomena

WALTER G. BOWERMAN has an article entitled "Sunspots in Review" in *Sky and Telescope* of September, which, although containing nothing new on the subject, provides an excellent summary of research in this particular branch. Much still remains to be done on the effects of sunspots, and in some cases results obtained by different investigators are of a contradictory nature. Thus, while some have discovered that the sun radiates more heat to the earth with increase in the number of sunspots, others have found no such correlation, and additional material is necessary before any definite conclusion can be drawn. H. H. Clayton, writing in *World Weather*, has pointed out that proof of variation in the sun's radiation with sunspot periods is found in the variation of the polar caps of Mars. When the spots are numerous and at the same time a polar cap is turned towards the sun, it lessens in size. He also states that variations in the light reflected by Jupiter have been found to be associated with sunspot periods. Dr. Stetson, in a letter to Mr. Bowerman, states that evidence from ionospheric investigations reveals an output of solar radiation, especially in the extreme ultra-violet, which is 100–150 per cent greater at sunspot maximum than at minimum. Huntington, writing in "Earth and Sun", suggests that the planets have an influence on sunspots—akin to trigger action—the energy derived from them being like pressing a button to start an explosion. Once a little eddy is started, the slight movement so generated may be reinforced by stresses due to rapid cooling of the sun's outer layer, or to the sun's varying rate of rotation at different latitudes. Mr. Bowerman admits that there are many pitfalls for the student of solar-terrestrial relations, and one must avoid too hasty generalizations. In different parts of the world relationships to temperatures, pressure, and precipitation are not always the same. For example, the Nile shows a maximum height near sunspot maximum, whereas rivers in temperate regions, such as the Parana in the Argentine, show the reverse. Great care is necessary before formulating definite conclusions.

## Industrial Electrical Maintenance

IN a paper read in London on December 14 before the Institution of Electrical Engineers, J. C. B. Nicol contends that industrial maintenance should be controlled through an organized system. From an analysis of the functions of a maintenance department, he derives the principles underlying good organization and illustrates some of these by examples. There are probably many types of equipment data records in use, and it is believed they are all fundamentally the same if different in detail. These differences must cause considerable trouble to manufacturers when supplying information to various customers, and if standard cards were agreed, manufacturers could easily supply them with their equipment. Manufacturers often supply maintenance instructions and connexion diagrams with their equipment, as well as lists of spare parts. If all such information were provided on standard-size pages, which could be bound into a strong loose-leaf book, it could then be given to workmen with a good chance of survival.

It would be advantageous if a standard code of practice for the maintenance of industrial electrical apparatus were compiled and issued by the British Standards Institution. Such a code could not make any comprehensive technical recommendations, but it could specify good administrative procedure, which would tend to standardize systems and facilitate the interchange of maintenance engineers. Some standardization on these lines would make the exchange of information between manufacturers and maintenance engineers easier, and would also help installation contractors and consultants to take an interest in maintenance work and its problems.

## Plastics in Electrical Industry

AN article by A. J. Warner (*Elec. Comm.*, 22, No. 1; 1944), in reviewing the physical and electrical properties of plastics, discusses the various types of plastic materials available, paying particular attention to their electrical properties, and also examines their physical limitations, since there is no 'all-purpose' plastic available for the variety of conditions encountered. In all cases, a compromise must be made between the electrical properties and the mechanical limitations inherent in the material. In the summary which is provided, which of necessity is incomplete and rather fragmentary, such data are collected and collated as will facilitate an intelligent selection of materials. It cannot be too strongly emphasized, however, that, in the present state of the plastic art, a mere tabulation of physical and electrical properties will not necessarily enable one to choose the right material for any particular application. There still exists and will always exist the need for the exercise of judgment and the use of the accumulated knowledge of the particular engineer having the problem under consideration.

For the highest degree of electrical performance, where dielectric properties are of paramount importance, the pure hydrocarbons such as polystyrene and polyethylene are the best materials available. Where cheapness, availability, and good overall physical properties are required for low-frequency applications, and where only moderate electrical performance is required, the recent developments in the urea formaldehydes should be considered. For large sheets of various thicknesses for panel mounting strips, etc., and where high electric strength, reasonably low moisture absorption, and reasonable electrical properties are required, Grade *XXXP* laminated plastics are recommended.

## Equilibrium Diagrams of Alloys

THREE more "Annotated Equilibrium Diagrams" have been published by the Institute of Metals. No. 2 deals with the copper-tin system, No. 3 with the copper-zinc alloys and No. 4 with the copper-aluminium. Prepared by Dr. G. V. Raynor, each sheet contains a large-scale diagram in its latest form, some notes upon it, and an extensive bibliography. At the almost nominal price of 6*d*. per sheet, they represent what is probably the best value attainable anywhere in metallurgical literature.

## Mineral Deficiencies in Pastures

TECHNICAL COMMUNICATION No. 15, issued by the Imperial Bureau of Animal Health (Rowett Institute, Aberdeen, 1944. 5*s*.), entitled "Minerals in Pasture, Deficiencies and Excesses in Relation to Animal Health", by Miss F. C. Russell, is a valuable review of this complex subject. The literature surveyed deals with diseases attributed or attributable to

deficiencies of cobalt (bush sickness of New Zealand, pining in the United Kingdom, etc.); of copper (swayback in the United Kingdom and other countries, which is a disease of lambs with paralysis of the limbs, inco-ordination and demyelination of certain tracts of the spinal cord, which J. R. M. Innes (*Vet. Record*, **55**, 369; 1943) has compared with certain rare diseases of man); of both copper and cobalt; and of potassium, sodium chlorine, iodine, phosphorus, calcium or magnesium (grass or lactation tetany). Other sections deal with diseases attributed or attributable to excesses of selenium, molybdenum, nitrate or manganese and with fluorosis and arsenical poisoning. A useful general summary completes the review, and the bibliographies of each section guide the reader to further study. The problems here discussed are difficult and are not for those who require circumscribed investigations which are certain to give results. Miss Russell has performed very well her difficult task of presenting the controversial literature about them, and everyone who is concerned with this kind of work will be grateful to her.

## Mexico's Vital Statistics

DR. RICARDO GRANILLO, head of the Mexican Department of Statistics and Demography, states that his Department is a part of the Secretariat of National Economy (*Bol. Of. San. Panamericana*, **23**, 419; 1944). It collects and publishes statistics, takes a national census, makes special studies, represents the country at international congresses, and has jurisdiction over population, public education, social welfare, industrial economy and vital statistics. The principal functions of the Vital Statistics Office of the Secretariat of Health and Welfare include keeping Federal and State health authorities informed of the general mortality and that from contagious disease and other important causes; reporting on epidemics in areas where there are no practitioners and regular reports of contagious diseases cannot be obtained; the study of the geographical and seasonal distribution of general, infant, endemic and epidemic disease mortality; reporting to the Panamerican Sanitary Bureau and other international offices and neighbouring health authorities on the general health conditions of Mexico; and keeping a record of public health activity throughout the Republic.

## Nizamiah Observatory, Hyderabad

THE director of the Nizamiah Observatory has communicated a paper, "Occultations of Stars and Planets by the Moon observed at the Nizamiah Observatory, Hyderabad, during the Year 1943" (*Mon. Not. Roy. Astro. Soc.*, **104**, 4; 1944), which gives the occultation results for 1943 from January 11 until December 31. Twenty-seven occultations of stars and one of Venus were observed by M. K. Bappu, using the 15-in. visual refractor. M. V. V. Sastry, assisted by S. Aravamudan, carried out the reductions. In the case of two stars, proper motions were applied to the co-ordinates given in the catalogue in computing the mean places for use in the reductions, and positions were taken from the "Nautical Almanac" for the others.

## The Night Sky in January

NEW moon occurs on January 14d. 05h. 06m., U.T., and full moon on January 26d. 06h. 41m. The following conjunctions with the moon take place: Jan. 4d. 20h., Jupiter 4° S.; Jan. 12d. 08h., Mercury 0·2° S.; Jan. 12d. 21h., Mars 2° S.; Jan. 17d. 14h., Venus 4° N.; Jan. 25d. 18h., Saturn 0·5° N. Mercury is in conjunction with Mars on Jan. 26d. 15h., Mercury being 0·4° N. The following occultations of stars brighter than magnitude 6 take place: Jan. 1d. 20h. 56·5m., 8 Leon. (*R*); Jan. 18d. 17h. 52·8m., 33 Pisc. (*D*); Jan. 21d. 17h. 27·5m., $\mu$ Ceti (*D*); Jan. 24d. 2h. 15·2m., *i* Taur. (*D*); Jan. 25d. 2h. 21·7m., + 20° 1105*m* (*D*); Jan. 26d. 18h. 24·0m., 63 Gemi. (*D*). The times refer to the latitude of Greenwich, and *D* and *R* refer to disappearance and reappearance, respectively. Mercury rises 1½ hours before the sun at the beginning, and 36 minutes before the sun at the end, of the month. It is stationary on Jan. 2 and reaches its greatest westerly elongation on Jan. 13. Venus is conspicuous in the evening hours, setting at 19h. 51m., 20h. 29m. and 21h. 08m. at the beginning, middle and end of the month, respectively. Mars rises about three-quarters of an hour before the sun at the beginning of the month and is not well placed for observation. Jupiter, in the constellation of Virgo, is a conspicuous object in the morning hours and rises at 23h. and 21h. at the beginning and end of the month, respectively. Saturn, in the constellation of Gemini, can be seen throughout the night, setting at 6h. 52m. in the middle of the month.

## Announcements

DR. W. A. WATERS, lecturer in chemistry in the University of Durham, has been elected to an official fellowship in organic chemistry at Balliol College, Oxford.

MR. A. W. LADNER retired from his position of principal of the Marconi Company's School of Wireless Communication at the end of the year, after thirty-two years service with the Company, and twenty-four years as superintendent of instruction. Mr. Ladner will continue to act in an advisory capacity. His place as principal of the School has been taken by Mr. N. C. Stamford, who was previously with the Company and has since been on the teaching staff of the Department of Electrical Engineering at the University of Manchester.

AT the annual meeting of the Genetical Society, the following officers were elected: *President*, Dr. C. D. Darlington; *Vice-Presidents*, Prof. T. J. Jenkin, Prof. R. A. Fisher and Mr. M. B. Crane; *Treasurer*, Miss E. R. Saunders; *Secretaries*, Mr. W. J. C. Lawrence, John Innes Horticultural Institution, Merton, S.W.19, and Mr. R. Race, Galton Laboratory Serum Unit, Department of Pathology, Cambridge.

THE following appointments have recently been made in the Colonial Agricultural Service: V. E. Gale, to be agricultural officer, Nigeria; D. H. Laycock, to be agricultural officer, Nyasaland; A. H. Strickland, to be entomologist, Gold Coast; J. W. D. Fisher, senior agricultural officer, Sierra Leone, to be principal agricultural officer, Sierra Leone; R. R. Glanville, principal agricultural officer, Nigeria, to be director of agriculture, Sierra Leone; and R. O. Williams, deputy director of agriculture, Trinidad, to be director of agriculture, Zanzibar.

ERRATUM.—In the article on the "Deciduous Cypress" in *Nature* of December 16, p. 775, for 12 ft. (line 8, col. 2) read 21 ft.

## A New Method for Measuring Diffusion Constants of Biologically Active Substances

THE study of diffusion constants of proteins and other materials of high molecular weight has added much to our knowledge of the nature of these substances (Svedberg and Pederssen[1], Polson[2]). These studies were made on materials which were obtained in the pure state. Unfortunately, when dealing with substances comprising several components, the usual optical method of diffusion (Lamm[3]) cannot be applied except with great difficulty. In such cases recourse must be made to analytical methods. The method of Northrop and Anson[4], namely, diffusion through a porous plate, has been of great value, but this method too has its limitations. Bourdillon[5] has proposed a method for the analytical determination of diffusion constants. His method, although theoretically sound, is very difficult to apply, especially when dealing with viruses. (For a criticism of the above-mentioned methods, see Markham, Smith and Lea[6].)

An account is given below of a method which has been found suitable for the measurement of the diffusion constant of horse-sickness virus.

*Theoretical:* From the well-known law of Fick

$$ds = -AD\frac{dc}{dx}\cdot dt,$$

and its solution

$$\frac{dc}{dx} = \frac{C_0}{2\sqrt{\pi Dt}}\,e^{-x^2/4Dt},$$

the following equation has been deduced

$$D = \frac{S^2}{C_0{}^2A^2}\cdot\frac{\pi}{t},$$

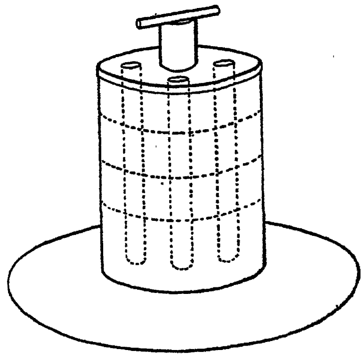
where $S$ is the amount of substance which diffused through a cross-section $A$ cm.² at the original boundary $X = 0$ in $t$ sec. $D$ is the diffusion constant and $C_0$ is the original concentration.

This equation can be applied to all substances which do not sediment appreciably under the influence of gravitation, such as the proteins, enzymes and the small viruses. Its range does not include the larger viruses like vaccinia and psittacosis, as their sedimentation constants are too high.

*Experimental:* To measure the amount of substance which passed a given layer in a diffusion vessel, the apparatus shown in the accompanying diagram was made. Four circular metal sections 1 cm. thick and 4 cm. in diameter were cut and holes 0·5 cm. in diameter drilled through them, except the bottom section, into which the holes extend three-quarters of the thickness of the section. The flat faces of these sections were well ground. They turn on a central bolt which is fixed in a wooden base. In a certain position the holes coincide to form four cylindrical cavities 4 cm. long and 0·5 cm. in diameter. The surfaces between the sections were smeared with a thin layer of wool grease.

The diffusion experiment was run as follows.

The virus solution was placed in the four cavities formed by the bottom two sections, and the cavities in the top two sections filled with suspension medium of a slightly lower density than the fluid in the bottom



cavities. The apparatus was placed in a constant-temperature room and when temperature equilibrium had been reached the top two sections were turned slowly so that the cavities corresponded with those in the lower two sections. In this way sharp interfaces were formed at the contact of the top fluid with the bottom fluid. The apparatus was left in that position for definite periods of time, after which the top fluid was again isolated by rotating the segments. The fluid in the top sections was sucked out with a syringe, the volumes measured and tested for virus content.

The accompanying table gives the results obtained:

| Exp. No. | Time (sec.) | $A$ (cm.²) | $C_0$ in mld.* per c.c. | $S$ in mld.* | $D\times10^7$ cm.²/sec. |
|---|---|---|---|---|---|
| 1 | 151,200 | 0·2 | 160,000 | 2232 | 1·01 |
| 2 | 151,200 | 0·2 | 440,000 | 6480 | 1·01 |
| 3 | 237,600 | 0·2 | 226,000 | 3360 | 0·73 |
| 4 | 331,200 | 0·2 | 200,000 | 2796 | 0·46 |
| | | | | | Av. 0·80 |

* Determined by the Read and Münch method of 50 per cent end-points.

The diameter calculated from the Stokes-Einstein formula for the diffusion of a substance gave the value $d = 53{\cdot}2\,\mu\mu$. This value agrees very well with those determined by other means, namely, ultracentrifugation $45{\cdot}4\,\mu\mu$, and ultrafiltration 40–60 $\mu\mu$ (Polson[7]).

From the sedimentation constant $S = 286 \times 10^{-13}$ Svedbergs, the specific volume $V = 0{\cdot}8$ and the diffusion constant $D = 0{\cdot}8 \times 10^{-7}$ cm.²/sec., the molecular weight is calculated according to the formula of Svedberg[1],

$$M = \frac{RTS}{D(1-V\rho)} = 44{,}500{,}000,$$

where $\rho$ is the density of the suspension medium.

This value for the molecular weight must be considered approximate, as the determination of $D$ depends on the relationship $\frac{(S)^2}{(C_0)^2}$, the determination of which could only be done by biological means.

A more extensive article will be published in the *Onderstepoort Journal.*

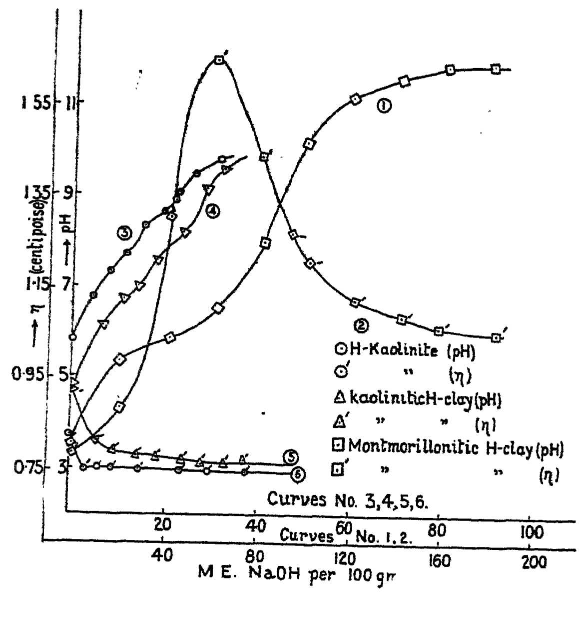
## ifferentiation of Hydrogen Clays and Identification of their Mineral Constituents by Electrochemical and Viscous Methods

A NUMBER of publications[1,2,3,4] from this Laboratory have dealt with the acid character of hydrogen clays isolated from Indian soils as revealed from a study of their titration curves with bases, buffer indices and base-exchange capacities calculated at the inflexion points of the titration curves. An 'electrochemical method' for differentiating hydrogen clays and identifying clay minerals contained in them has been developed, based on a comparison of their electrochemical properties with those of hydrogen colloids isolated from natural deposits of the clay minerals. Hydrogen kaolinites (prepared by repeatedly leaching entire clay fractions with 0·04 *N* hydrochloric acid and washing free from chlorides) from four different samples of kaolin and a number of hydrogen clays known, from X-ray and dehydration studies carried out by Mr. S. N. Bagchi, to contain kaolinitic minerals, have a dibasic acid character within the range of *p*H 4–11·0[5,6]. The first inflexion usually occurs between *p*H 7·0 and 8·0 and the second between *p*H 8·0 and 9·5 (see diagram). The ratio of the base-exchange capacities at the two inflexion points is nearly 2·0, though the actual value of the base-exchange capacity varies in the case of different hydrogen clays and hydrogen kaolinites from 12·0 m.e. to 23·0 m.e. per 100 gm. at the first inflexion point; and from 20·0 to 45·0 m.e. per 100 gm. at the second inflexion.

Hydrogen clays containing only montmorillonitic minerals as judged from X-ray analysis show only one inflexion between *p*H 7·1 and 8·8 in their titration curve with caustic soda (see graph) and between *p*H 5·2 and 7·5 when titrated with barium hydroxide and calcium hydroxide[7,8]. The base-exchange capacity calculated at this inflexion point varies from 55 m.e. to 100 m.e. per 100 gm. for entire hydrogen clay fractions.

Another criterion for differentiating kaolinitic clays from those containing montmorillonitic minerals has been found and is based on the effect of addition of



caustic soda on the viscosity of aqueous suspensions of the hydrogen clays. On the gradual addition of the alkali to hydrosols of hydrogen bentonites[9] and montmorillonitic hydrogen clays[10], their viscosity increases and passes through a maximum value at a point corresponding to about 75 per cent neutralization of the amount of the acid given by the inflexion point of the titration curve. Apart from a slight initial decrease, the alkali has no marked effect on the viscosity of hydrogen kaolinite and hydrogen clays containing only kaolinitic minerals within the range *p*H 4–11. The viscosity of one of the hydrogen kaolinites, *D*, slightly increased on the addition of the alkali, after which the viscosity remained practically constant. X-ray analysis showed that it contains montmorillonite in addition to kaolinitic minerals. Six subfractions having average equivalent spherical diameters 1·4, 0·70, 0·50, 0·32, 0·21 and less than 0·18 microns were isolated by the graded centrifugalization of *D*. A concentration of montmorillonite in the finer subfractions was indicated by the chemical compositions; nature of potentiometric titration curves with caustic soda; base-exchange capacities; and the effect of the alkali on the viscosity.

## Antioxidants and Prevention of Rancidity in certain Pacific Coast Fish

DURING recent years it has been established that herring muscle[1] and pork muscle[2] possess a lipoxidase enzyme (or enzymes) which is capable of accelerating post-mortem oxidation of the tissue fats. This enzyme catalyses the formation of peroxides from the unsaturated fatty acids present, and consequently facilitates the development of rancid odours and flavours in the flesh. The enzyme concerned is sensitive to heat, will function actively at temperatures well below 0° C. and its action is markedly accelerated by pure sodium chloride. This last-named property has been used to explain the fact that certain cured fish and meats are particularly liable to become rancid during storage.

On the north Pacific coast of America the flesh of many of the most valuable food fishes is rich in fat, and consequently cold storage of such fish under conditions which will prevent the formation of rancid fat has always presented a problem. The practice of lightly brining fillets prior to freezing them in order to prevent drip when they are thawed is by no means uncommon on this continent[3], and this procedure is well known to lead to the premature development of a 'salt fish' flavour and rancidity in treated fillets.

TABLE 1.

| Expt. | Treatment | Peroxide value after storage for 64 days at average temperature of − 3° C. |
|---|---|---|
| 1 | Minced flesh untreated | 4·95 |
| | Minced flesh with 1 per cent sodium chloride incorporated | 20·3 |
| | Minced flesh with 0·02 per cent ethyl gallate incorporated | 0·1 |
| | Minced flesh with 1 per cent sodium choride plus 0·02 per cent ethyl gallate incorporated | 0·2 |
| 1 | Fillets untreated | 13·3 |
| | Fillets dipped in 20 per cent sodium chloride | 33·6 |
| | Fillets dipped in 20 per cent sodium chloride containing 0·5 per cent ethyl gallate | 0·3 |
| | Fillets dipped in 20 per cent sodium chloride followed by 0·25 per cent ethyl gallate | 1·35 |
| | Fillets dipped in 0·25 per cent ethyl gallate followed by 20 per cent sodium chloride | 6·15 |
| | Fillets dipped in 20 per cent sodium chloride containing 0·25 per cent ethyl gallate | 0·3 |
| | | After storage for 46 days at average temperature of − 5° C. |
| 2 | Fillets untreated | 17·6 |
| | Fillets dipped in 1 per cent ethyl gallate | 2·2* |
| | Fillets dipped in 0·5 per cent ethyl gallate | 2·0* |
| | Fillets dipped in 0·1 per cent ethyl gallate | 6·5 |
| | Fillets dipped in 1 per cent sodium gallate | 13·0 |
| | Fillets dipped in 0·5 per cent sodium gallate | 17·6 |
| | Fillets dipped in 0·1 per cent sodium gallate | 17·0 |

* In this experiment, bait herring which had been frozen for some months in blocks were used, the initial peroxide value of the fat being 2·0, while in the first experiment strictly fresh herring in which the peroxide value was zero were used.

In this connexion, recent work[4] has shown that fillets of certain species of Pacific salmon readily become rancid when they are stored at temperatures which are commonly employed commercially (−12° and −20° C.), and that this susceptibility is significantly increased when the fillets are lightly brined prior to freezing. The practice of 'glazing' whole fish with a thin layer of ice undoubtedly retards the development of rancid fats. Storing fish at low temperatures (−28° to −30° C.) has also been found to exert a desirable effect[5], but such temperatures are seldom realized commercially.

In view of these facts, experiments were commenced in order to determine the possible value of antioxidants as a means of inhibiting the development of a rancid condition in the flesh of local fatty fish. For convenient practical application an antioxidant which is sufficiently soluble in water so that it can be added to a liquid in which the fish are immersed, and yet which is highly soluble in fat so that it will be readily absorbed by the flesh, was sought. It was also realized that such an antioxidant would have to be fairly cheap and relatively non-toxic. Recently ethyl gallate, 1 : 5-dihydroxynaphthalene and guiacum resin have been used experimentally to hinder the development of oxidative rancidity in certain foods[6,7]. Of these substances, ethyl gallate was selected for the present work since it possesses the following properties. It is fairly soluble in both water and in fats, has little or no adverse effect on the flavour of foods in concentrations which strongly inhibit fat oxidation, is not very expensive and is comparatively non-toxic for mice[8]. In addition, it is known that gallic acid itself is practically non-toxic and that about one third of the aqueous extracts of tea leaves consists of tannins which are rich in gallic acid. Some experiments were also made using sodium gallate, which would in practice be somewhat cheaper than the ester.

In the experiments described below, fish fillets were immersed from one minute in the solutions, a draining period of one minute being permitted between two successive dips. Sodium gallate solutions were prepared by bringing solutions of gallic acid to *p*H 6 with sodium hydroxide. Treated fillets were wrapped in moisture-proof 'Cellophane' paper during storage. Peroxide values on the extracted fat were determined by Lea's method[9], the results being reported as ml. of 0·002 *N* sodium thiosulphate per gm. of fat. The results of two experiments with herring are given in Table 1.

It will be seen that in the case of minced flesh the addition of 1 per cent sodium chloride greatly increased the peroxide value obtained on storage. The incorporation of 0·02 per cent ethyl gallate in the flesh strongly suppressed peroxide formation even in flesh treated with sodium chloride. Immersing fillets in sodium chloride brine greatly increased the peroxide value of the stored fish, while addition of 0·5 per cent ethyl gallate to the brine strongly retarded peroxide formation. Results obtained using 0·25 per cent ethyl gallate solutions showed that lower peroxide values resulted when fillets were treated with ethyl gallate after brining than when treated prior to or during the brining procedure. Sodium gallate solutions were not nearly so effective as ethyl gallate solutions, presumably due to the low solubility of the sodium salt in fat.

The results of an experiment in which white spring salmon fillets were treated with various solutions and then stored at 0° C. are given in Table 2. The results at this temperature were naturally complicated by the fact that considerable bacterial growth occurred, and it is known that reducing systems of bacteria normally inhibit peroxide formation[9]. It will be seen that so far as accumulation of peroxides was concerned, the use of sodium chloride temporarily accelerated their formation, but that after fifteen days, when bacterial decomposition was very marked, similar values were obtained in both the brined and untreated fillets. At the natural *p*H of the fish flesh (about 6·2), sodium nitrite, which has marked bacteriostatic properties[10], exerted a slight antioxidant effect. For the short storage period

TABLE 2.

| Treatment | Peroxide value after | | Bacteria in millions per gm. by direct count after | |
|---|---|---|---|---|
| | 6 days | 15 days | 6 days | 15 days |
| Untreated | 0·4 | 0·95 | 125 | 380 |
| Dipped in 0·5 per cent ethyl gallate | 0 | 0 | 1·7 | 410 |
| Dipped in 0·5 per cent sodium gallate | 0 | 0 | 3·8 | 980 |
| Dipped in 0·5 per cent sodium nitrite | 0 | 0·15 | 0·3 | 2 |
| Dipped in 20 per cent sodium chloride | 1·3 | 0·95 | 6·2 | 540 |
| Dipped in 20 per cent sodium chloride containing 0·5 per cent ethyl gallate | 0 | 0 | 0·1 | 210 |
| Dipped in 20 per cent sodium chloride containing 0·5 per cent sodium gallate | 0 | 0·1 | 1·7 | 640 |

studied, ethyl gallate and sodium gallate proved effective antioxidants. Sodium nitrite strongly retarded bacterial decomposition. Ethyl gallate, and to a somewhat slighter extent sodium gallate, inhibited bacterial growth. In this connexion it must be noted that experiments with minced salmon flesh have shown that the incorporation of 0·02 per cent ethyl gallate retards both bacterial growth and the onset of oxidative rancidity. The bleaching of the astacin pigments of salmon during cold storage is largely prevented by ethyl gallate.

It is intended to publish the detailed results of these experiments in the *Journal of the Fisheries Research Board of Canada*.

## Apparent Respiration of Wheat Grains and its Relation to a Fungal Mycelium beneath the Epidermis

THE experimental evidence summarized below has led us to the conclusion that the carbon dioxide produced by stored wheat, apparently by respiration of the grain itself, is in fact produced almost entirely by micro-organisms growing in the pericarp ('bran') of the grains.

Respiration measurements made on wheat stored at 25° C. show a progressive increase in the rate of carbon dioxide output over a period of several months. The increased respiration-rate persists if the wheat is removed to a lower temperature, and may be many times greater than that of wheat which has been stored for the same period at the lower temperature. The effect is greatest in wheat having a water content higher than 15 per cent (wet-weight basis), but we have observed progressive increase in respiration-rate of wheat drier than this when stored at 25° C. for periods of six months or more. This is confirmed by some of the results of Robertson, Lute and Gardner[1].

Progressive increase in respiration-rate suggests progressive development of actively respiring tissue, but it has not been possible to detect any corresponding increase in the size or differentiation of the wheat embryo.

Wheat grains from which the embryo has been removed by the attack of larvæ of a moth, *Ephestia elutella* Hb., have a respiration-rate nearly as high as that of undamaged grains hand-picked from the same sample. Since the embryo is the only part of the wheat grain which would be expected to be actively respiring, this suggests that the chief source of respiratory carbon dioxide is external to the seed proper and is much greater than that of the embryo.

Leach[2] has recently reported respiration measurements on wheat grains the embryos of which were removed by drilling, and has similarly shown that there is little, if any, fall in respiration-rate on removal of what is presumably the most active tissue of the fruit. From this Leach has come to a conclusion similar to our own, namely, that the respiration of wheat which is too dry to germinate is due almost entirely to micro-organisms that infect it. Since wound reactions and other effects may follow removal of the embryo, we do not consider this evidence, by itself, a sufficiently firm basis for the conclusion.

The pericarp of wheat grains is largely removed by abrasion if a sample of grain is shaken with coarse carborundum powder in a sealed glass bottle for about 48 hours. We have found that this process reduces the rate of carbon dioxide output to about 5 per cent of its original value. Such wheat is not injured or dead, for it will germinate as rapidly and completely as before treatment provided that the abrasion process has not been carried too far.

That the lowering of respiration-rate is not due to a toxic effect of carborundum powder is shown by the fact that a similar effect may be obtained by the use of crushed flint or glass powder. Also, if carborundum is mixed with whole wheat the respiration-rate is unaffected.

This experiment shows that the carbon dioxide produced by wheat originates largely in the pericarp; yet microscopical examination of sections of this structure shows few, if any, cells which appear to be actively developing or even living.

The epidermis of the pericarp may usually be stripped from a grain of wheat, sometimes almost entire, after soaking for a few minutes in water. Staining with aniline blue will usually reveal a number of fungal hyphæ, and in some samples an extensive mycelium, on the *inner* surface of the epidermis. Unless grains are obviously mouldy, no hyphæ can be found on the *outer* surface of the epidermis. It seems likely that this fungal mycelium is part, at least, of the micro-flora the existence of which is suggested by the experiments described. We have demonstrated the existence of a similar flora under the epidermis of maize, particularly over the embryo and basal parts of the seed.

The mycelium is abundant in many samples of English wheat immediately after harvest, when the water content may range from 15 to 25 per cent or even higher, and is detectable, though in rather small quantity, in Canadian and other wheats with a water content in the region of 12 per cent. The abundance of mycelium may be a measure of the dampness of the grain during the period immediately before harvest.

It is important to note that we have demonstrated a mycelium which is absent from the surface of the grain. Previous reports of fungi associated with wheat, and measurements of their amount, have been based on the numbers of colonies obtained by shaking grain with sterile water. Such investigations probably reveal only superficial spores which, until they have germinated, can make no measurable contribution to the apparent metabolism of the wheat grain. Such estimates of fungal and bacterial population are irrelevant to the probable life of grain or other seeds in storage, unless the humidity becomes high enough to permit spores to germinate rapidly.

Since the mycelium is vegetative, we have been unable to identify any of the organisms which compose it or even to verify that they are fungi, and we have not so far been successful in isolating them free from contamination by the spores which are

invariably present on the outer surface of the epidermis. We are, however, attempting to grow wheat to maturity under aseptic conditions from sterilized seed in order to obtain a small crop of grain free from contamination for comparison with normal wheat. When data for this comparison are available we will publish our detailed results elsewhere.

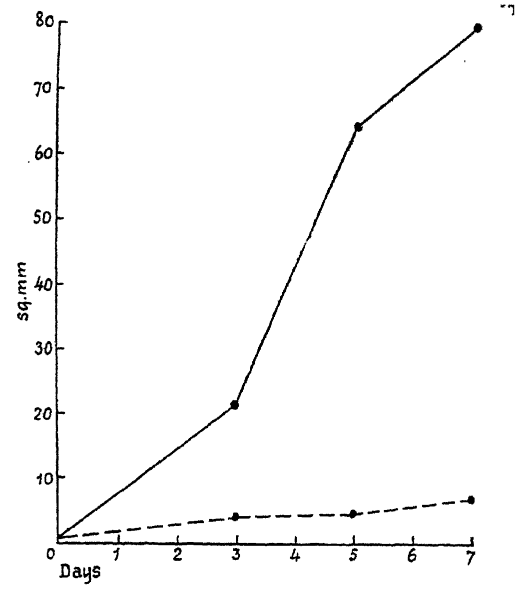
## Concurrence of Growth-promoting and Growth-inhibiting Factors in Extracts of Adult Rat Tissues

IN previous papers[1] from this laboratory it was shown that saline extracts of adult tissues and organs have a marked growth promoting effect on cell colonies *in vitro*. Under given experimental conditions, the growth-promoting activity of certain adult tissue extracts is several times that of embryonic tissue extracts of the same concentration. Although most tissues and organs of the adult organism display the growth-promoting power, the activity of the extracts varies from organ to organ. It is particularly high in heart, brain and smooth muscle, and low in kidney, bone marrow and liver.

Organs of almost all species tested (dog, sheep, cow, rabbit) were found to yield active extracts[2]. Extracts of rat organs, on the other hand, are exceptional in their behaviour with regard to cell-growth activation[3]. Of rat organs and tissues, only brain and embryo tissue displayed marked growth-promoting power; extracts of all other rat organs have either no growth-promoting property or inhibit the growth of cells *in vitro*. The unequal growth-promoting power of extracts of different origin could be accounted for by either of the following assumptions: (1) that the growth-promoting principles are present in amounts varying from organ to organ and species to species; (2) that the difference in activity is due to the simultaneous presence in varying concentration of growth-inhibiting factors, which counteract cell proliferation.

Our experiments have shown that the absence of growth-promoting ability in extracts of most organs of adult rats can be explained in accordance with the second assumption. In the investigations reported below, the procedure previously used[4] by us for the partial purification of active principle from growth-promoting adult tissue extract was used. The experiments were performed with extracts of rat heart muscle, which have either no stimulating action or even inhibit cell growth. Minced heart muscle was extracted with four volumes of normal saline and this extract was precipitated with four volumes of alcohol. The precipitate obtained was then treated in a Soxhlet apparatus with acetone or petroleum-ether. The extracted material after drying was taken up in 'Tyrode'. Solutions thus obtained were added to standardized cultures of chicken fibroblasts in Carrel flasks. The growth of the cell colonies in medium containing this solution as supernatant fluid phase was compared with the growth of controls (sister



EXPERIMENT 11245 A. GROWTH OF CHICKEN FIBROBLASTS (FULL CURVE) IN MEDIUM CONTAINING SOLUTION OF ALCOHOL PRECIPITATE OF RAT HEART EXTRACT, TREATED WITH PETROLEUM-ETHER; AND GROWTH IN PROTECTIVE MEDIUM (BROKEN CURVE).

halves) growing in protective medium composed of plasma diluted with 'Tyrode' 1 : 2 and covered with 'Tyrode' solution. The growth of cultures was recorded according to the method of Ebeling.

It could be shown that originally inactive rat tissue extracts are rendered active by the above treatment. Even alcohol precipitates of the extracts had slight growth-promoting activity. Subsequent treatment with petroleum-ether or acetone proved to be decisive. Petroleum-ether and acetone convert material originally inert and only slightly active after alcohol treatment into definitely active preparations.

The curves of the accompanying graph show the growth of a culture stimulated with a petroleum-ether-treated alcohol precipitate of rat heart extract compared with that of a control. These curves illustrate the optimal activation obtained, the average stimulation amounting to 450 per cent.

It may be concluded that the inability of rat tissue extracts to stimulate the growth of cells *in vitro* is due to the fact that in rat tissues (heart muscle) the growth-promoting substance is masked by the predominance of growth-inhibiting factors. The latter are probably of a lipoid nature.

Details of our experiments are being published elsewhere.

This work was done during the tenure of a Cancer Laboratories fellowship and was aided by a grant from the Dazian Foundation for Medical Research, New York.

## Production of 'Endomitosis' in Bean Roots and its Bearing on the Genesis of Tumours

Biesele, Poyner and Painter have shown[1] that diplochromosomes and higher polytenes are often to be found in tumours and that these large chromosomes are the result of endomitosis. Biesele and Cowdry[2] also found these abnormalities in the epidermis of mice painted with methylcholanthrene, as early as two days after painting.

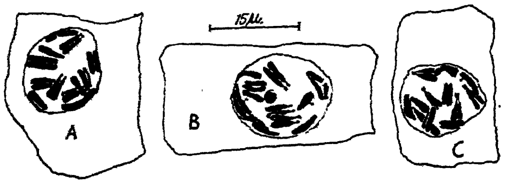
Recently, using bean roots, endomitosis was found by chance in roots allowed to become partially dry. Following up this observation, it was found that exposure to a colloidal suspension of benzpyrene and to hypertonic sugar solution also gave rise to this change.

I use the term 'endomitosis' because it was used by Biesele and others to describe[1] their findings. They found fully condensed chromosomes in nuclei having intact walls. The figure below shows similar abnormalities in treated bean roots.

The details of treatment were as follows. For partial drying, use a root about 20 cm. long—to obtain this length it is necessary to remove all lateral roots—pass it down glass tubing so that only 2 cm. are immersed in distilled water; leave it thus for 12 hours and then examine histologically. For benzpyrene treatment, substitute for the distilled water a colloidal suspension of 0·05 per cent in distilled water (good suspensions cannot be made in the presence of salts); under these conditions, the action of benzpyrene and of partial drying are combined, and abundant endomitoses are produced. Benzpyrene treatment without partial drying is obtained by filling the tubing to the top with colloid, but longer exposures of 24–48 hours are required. The effect is not obtained with short roots and before leaves have formed; it seems that an abundant volume of water must be absorbed—and this does not occur with short roots—for a sufficient amount of benzpyrene to enter. The suspended particles do not appear to enter, but only benzpyrene in solution. Occasional endomitoses were obtained by placing the roots in 8–10 per cent dextrose.

It is to be noted that two of the agents are potent to produce increased viscosity of the cytoplasm; as regards benzpyrene, information is wanting. Further, Guyer and Claus, using the ultracentrifuge, have shown[3] that tumour cells present great stiffening of the cytoplasm in comparison to cells of normal tissues, and that this applies not only to experimentally produced hepatomas, but also to liver cells in pre-cancerous stages.

It is likely, therefore, that endomitosis, polytene, polyploid and polynuclear cells of tumours are secondary to an increased stiffness of the cytoplasm and no more than signs of such a change.



THE FIGURE SHOWS THREE CELLS FROM ROOT TIP OF BEANS, STAINED WITH IODINE GENTIAN VIOLET: *A*, TREATED FOR 20 HOURS WITH BENZPYRENE; *B*, FOR 12 HOURS BY PARTIAL DRYING; AND *C*, WITH 8 PER CENT DEXTROSE FOR 24 HOURS. THE CHROMOSOMES ($2n = 12$) ARE ABNORMALLY CONDENSED AND THE CHROMATIDS CLOSELY APPLIED AS IN LATE METAPHASE. AT THE SAME TIME A FINE NUCLEAR WALL IS PRESENT. IN *B* THE NUCLEOLUS HAS NOT BEEN ENTIRELY ABSORBED. IN *A* AND *B* THE CENTROMERES APPEAR TO HAVE DIVIDED AND IN *C* TO BE UNDIVIDED. IN *B* AND *C*, LATERAL TRABANTS ARE PRESENT.

Increased viscosity of the cytoplasm was observed[4] as a common reaction of ciliates to a wide range of tumour-producing agents, and led to races of multiple organisms.

## Effect of some Pure Substances on Plant Growth

INCREASING concentration of heteroauxin in lanolin – water paste causes progressive inhibition of the growth of hypocotyls of dark-grown *Helianthus* seedlings. At moderate concentrations definite swellings are produced. These effects can be considered as being the result of a progressive disorientation of the cytoskeleton with corresponding loss of cell polarity. A higher degree of disorganization would naturally lead to autolysis. In the presence of the sodium salts of alizarin and quinizarin sulphonic acids, the above effects can be so modified that it requires a higher concentration of heteroauxin to produce an effect similar to that produced with lower concentrations of heteroauxin alone. Tests with the alizarin sulphonate indicate that in aqueous solution it does not destroy heteroauxin to any great extent when this is estimated colorimetrically.

The growth of oat roots can be inhibited by *o*-, *m*- and *p*-phenylene-diamine, benzidene, benzoquinone and other substances, these simultaneously staining the cell wall. In an extremely dilute solution of phenanthraquinone, roots gave a growth value only 16 per cent of those grown in tap water. Gallic and di-gallic acids in 0·01 per cent solution gave values of about 50 per cent. These substances have the property of reacting with proteins and would act as molecular cross-linkages[1] between the proteins of the embryonic cells of the root tip, thus preventing development of the normal dynamic cytoskeleton.

On a hypothesis that auxin by some means disengages certain bonds of attachment between the proteins or components of the cytoskeleton, the various effects of auxins become more understandable. Normal extension of a cell would result from the action of auxins on the three-dimensional lattices[2,3] of the cell wall and cytoskeleton. An artificial cytoskeleton such as would be formed in the root tips with some protein reactants would be stable and non-reactive to auxins. It is possible that alizarin and quinizarin sulphonic acids act more selectively on the hypocotyl cells.

## Formation of Creatinine in the Animal Body

H. Borsook and J. W. Dubnoff[1] have discovered that phosphocreatine is changed into creatinine in water solution at 38° and $pH$ 7, by splitting off phosphate, and they consider that this spontaneous reaction is the way in which creatinine is formed in the animal body. In connexion with this important discovery, I want to direct attention to similar results which I published in 1940, and which for obvious reasons did not reach any abstracting journal published abroad.

I found[2] that in minced muscle (38° C.) in the presence of fluoride, iodacetate or hydrogen cyanide, the formation of creatinine was greatly accelerated, and I tried to explain that fact by a non-hydrolytic dephosphorylation of phosphocreatine. The idea that creatinine is formed not by splitting off water from creatine but by the splitting of phosphate from phosphocreatine is now made fully evident by Borsook and Dubnoff's experimental work.

## Prolongation of the Effect of Narcotics by Combination with Mucic Acid

A SEARCH for improved methods of prolonging the effect of the injection of morphine and other narcotics resulted in the observation that, for a given dose of morphine, the period of narcosis can be considerably extended if the base is administered in the form of mucate instead of the usual salts such as tartrate, sulphate, etc. This prolongation of effect is also obtained with the mucic acid compounds of other physiologically active bases such as adrenaline and ergometrine.

Some of these compounds are now undergoing systematic pharmacological and clinical test, the results of which will be published elsewhere in due course. In the meantime, other compounds of mucic acid, its homologues, analogues and their derivatives are being prepared and examined to ascertain if this particular property is exhibited by them all to a greater or lesser extent.

## Inheritance of the 'Bolter' Condition in the Potato

'BOLTERS' occur[1,2] in many potato varieties and are distinguished from the normal plants of the variety by the following characteristics: the haulms are more vigorous, taller and with longer internodes, the tubers are coarser and the crop heavier at maturity, maturity is much later, and flowering is much freer. The 'bolter' condition is perpetuated by the tubers, and Davidson[1] states that bolters obtained in 1917 from the variety Snowdrop have always produced bolters.

This group of characters by which the 'bolter' differs from the normal plant of the variety might be due to the pleiotropic effects of a single gene, but a more attractive hypothesis is that it is due to the loss or gain of a whole chromosome. Root-tip counts of 'bolter' plants of the varieties Gladstone and Ulster Chieftain showed, however, that the chromosome number was $2n = 48$ and was identical with that of the normal plants of the varieties (these counts were made by Mr. N. W. Simmonds and checked by one of us, H. W. H.).

'Bolters' also differ from normal plants in having 'wilder' underground parts, that is, the stolons are more numerous, longer and more persistent. The root system also appears to be more strongly developed. These differences have been utilized in comparing the two crosses, Gladstone female × Flourball and Gladstone 'bolter' female × Flourball. A third family from the cross U.S.D.A. seedling 41956 female × Flourball is also available for comparison.

The crosses were made in 1942 (the 'bolter' Gladstone having been collected in 1941 from a field of Gladstone in Northern Ireland) and the seedlings were raised in pots in 1943 in an insect-proof glasshouse. In 1944 two tubers from each seedling were planted out in the field for scoring and the results are shown in the accompanying table.

| Family | Cross | No. of distinct seedlings | Percentage of plants with underground parts: cultivated | somewhat wild | wild | very wild |
|---|---|---|---|---|---|---|
| 50/43 | Gladstone 'bolter' × Flourball | 25 | 20 | 44 | 24 | 12 |
| 49/43 | Gladstone × Flourball | 52 | 58 | 25 | 17 | 0 |
| 47/43 | U.S.D.A. 41956 × Flourball | 133 | 62 | 20 | 17 | 1½ |

Families 49/43 and 47/43 have similar percentages of plants in the four groupings of underground parts, but family 50/43 from the 'bolter' Gladstone cross differs in having many fewer plants with the cultivated type and more plants with the somewhat wild, wild and very wild underground parts. Thus there seems no doubt that 'bolter' Gladstone differs in being genetically 'wilder' than normal Gladstone. On August 10 families 49/43 and 50/43 were scored for flowering; 38 per cent of the plants in family 49/43 had flowered as compared with 57 per cent in family 50/43.

Mr. John Clarke (the well-known Northern Ireland potato breeder) of Broughgammon, Ballycastle, Co. Antrim, has told us in conversation this year that he obtained similar results when comparing the cross Epicure 'bolter' × Herald with the cross Epicure × Herald. More than 50 per cent of the plants in the family from the 'bolter' cross were 'wild' types as compared with a small percentage from the cross Epicure × Herald.

Since a series of intermediates between the normal and bolter type occur and since it is known that maturity, flowering and stolon development are influenced strongly by the length of day, it is possible that the 'bolter' condition arises through the mutation of the gene or genes governing the photoperiodic reaction.

## Body-Weight as Determinator of Physical Efficiency

IN view of the nutritional, educational and other implications of physical development, it is desirable to arrive at an objective evaluation of anthropometric measurements. Among the determinators of muscular efficiency which a study of physical fitness of school children in South Africa has revealed[1], body weight has been found to be of significance. We apply three performance tests intended to yield information with regard to neuro-muscular skill and speed (100 yards running), circulatory and respiratory endurance (600 yards running) and muscular strength (putting the 12 lb. shot). As the accompanying table and graph indicate, a specific determination of performance standards through body-weight is noticeable. In the 100-yard race, underweight and overweight are about equally disadvantageous. In the 600-yard race overweight is more disadvantageous than underweight, while in putting the shot only underweight is disadvantageous. The medium body-weight levels are associated with the best all-round physical efficiency.

The tests were conducted with 1,514 boys of between 6 and 17 years of age. Baldwin and Wood's age-weight tables were used as standards. The four weight sub-groups ($A-D$) were calculated according to Bogert's[2] recommendation.

A detailed account of our findings, with special reference to nutritional problems, will appear in *Manpower* (Pretoria), the official organ of the National Advisory Council for Physical Education.

## Analogy between Pseudopodia and Nerve Fibres

A GOOD many years ago, Verworn[1] developed in some detail a supposed analogy between rhizopod pseudopodia and nerve fibres. He suggested that these represent two extreme types of living substance in which the effects of stimulation are transmitted respectively with and without decrement.

Though this suggestion has not proved fruitful as a basis of further research, some points in a recent letter by J. Z. Young[2] on the structure of nerve fibres revive the possibility that it may not be entirely without significance. Both nerve fibres and foraminiferan pseudopodia[3,4] apparently owe their form to the linear arrangement of micellæ, and are thrown into coils when this orientation is disturbed. In both, the internal protoplasm is in a more or less fluid condition and streaming movements can be observed.

Some observations made in the course of a prolonged study of foraminiferan pseudopodia at the Ghargaqa (Red Sea) Marine Biological Station some years ago may be compared with those of Young on the effects of cutting a nerve fibre. When a pseudo

podium is cut, the proximal part is rapidly withdrawn. Sometimes this takes place rather violently, and the pseudopodium is then thrown into loose spiral coils in the process. In the part distal to the cut the streaming movements continue unchanged for some time; but gradually the movement becomes preponderatingly towards the cut, and protoplasm accumulates there in the form of a swollen mass. Little or no movement can be seen in this mass, which is therefore probably more solid than the ordinary pseudopodial protoplasm. Subsequent slow general contraction of the whole of the pseudopodial reticulum distal to the cut results in the withdrawal of this part away from the place of the cut; but usually before this contraction is complete new pseudopodia begin to grow out from various parts of this now enucleated fragment. I have no record of coiling ever occurring during this slow contraction.

Thus, in contrast to the cut nerve fibre, in a cut pseudopodium it is the part connected with the nucleus which shrinks, while the swelling occurs at the distal side of the cut. Coiling only occurs in the nucleated fragment, and then only if the retraction is sudden. The fact that new pseudopodia grow from the enucleated fragment shows that contact with the nucleus is not required in order to orientate the micellæ or chain molecules, the existence of which has to be assumed in order to account for the structure and movements of the pseudopodia.

The weakness of Verworn's analogy lies largely in the fact that the pseudopodium is not to any extent specialized for the purpose of conduction. A stimulus given to one part of the pseudopodial reticulum has no effect on adjacent parts unless it involves a gross mechanical disturbance or a change in the streaming movements sufficient to extend to those parts. Nevertheless, from the point of view of the conditions necessary for maintaining physical stability in fine elongated strands of protoplasm, the larger Foraminifera provide particularly attractive material for study.

## Energy Imparted by Active Nitrogen

Spectroscopic evidence[1] shows that the maximum energy of excitation which a molecule of active nitrogen can impart to another molecule (or atom) is 9·45 eV. Lord Rayleigh, however, from a study of the incandescence of metals immersed in active nitrogen, finds[2] that each molecule of active nitrogen delivers to the metal energy of, at the least, 10 eV. These apparently conflicting results can be reconciled and satisfactorily explained on the hypothesis recently proposed by me, namely, that active nitrogen is simply the ionized molecule of nitrogen $N_2^+(X')$ produced by the discharge[3].

The molecules (or atoms) introduced into the vessel containing active nitrogen are excited by a three-body collision process as follows:

$$N_2^+ + e + M \rightarrow N_2\ (\text{excited}) + M\ (\text{excited}).$$

Now, the lowest electronic level of excitation to which $N_2$ can drop, on neutralization, is the $A$-level, with energy 6·1 eV. The levels lying immediately below it are high vibrational levels of the ground state ($X$) with distances of nuclear turning-points very different from the nuclear separation of $N_2^+(X')$. Transitions to any of these levels will violate the Franck-Condon principle. The maximum energy left over for exciting the third body is thus $15{\cdot}58 - 6{\cdot}1 = 9{\cdot}48$ eV. This explains why repeated attempts by spectroscopists have failed to produce excitation levels above 9·45 eV.

The possible levels below the $A$-level to which the neutralized $N_2$ molecule can drop are the ground-level ($X$) and a few of the vibration-levels immediately above it. But this would mean that nearly the whole of the energy of ionization is either radiated away or is taken up by $M$. The reaction in this case would be:

$$N_2^+ + e + M \rightarrow N_2\ (\text{normal state}) + M\ (\text{excited state}).$$

I do not know if the probability of such reactions has been studied. In my opinion the probability would be very small.

To explain the higher value of energy as obtained by Rayleigh we recall that for neutralization of $N_2^+$ on the surface of a solid, the latter acts as the third body. The electrons first arrive on the surface of the solid and remain there as surface charge. The $N_2^+$ ions then arrive and combine with the electrons, giving up the energy of recombination to the solid surface. Since the solid, with its complicated structure, has many modes of vibration, it can take up the whole of the released energy, 15·58 eV. This, in other words, means that though spectroscopically active nitrogen can impart energy only up to a maximum of 9·45 eV. to an atom or a molecule, it can impart much greater energy (15·58 eV.) to the surface of a solid. This explains the apparently conflicting results mentioned above.

## Permeability of Adsorbing Substances

King has shown[1] that at low concentrations the diffusion constant of water in keratin becomes extremely small in comparison with its value at higher concentrations. This effect is already known from the behaviour of the hair hygrometer[2], the response of which (dependent on the internal diffusion of water in keratin) is much slower at low than at high relative humidities. The magnitude of this effect is shown by the following figures I have obtained for the times ($\tau$) of half-change of the length of hair (of 0·1 mm. diameter) after a sudden small change of humidity, at 18° C.

| Per cent relative humidity | $\tau$ (sec.) |
|---|---|
| 10–25 | 150 |
| 25–34 | 65 |
| 34–49 | 40 |
| 49–63 | 26 |
| 63–75 | 15 |
| 75–92 | < 10 |

That this phenomenon is characteristic not only of keratins but also of other adsorbing substances, for example cellulose, can be shown by a very simple experiment, reminiscent of King's[1], but more suit-

able for obtaining quantitative results. A glass tube is divided into three compartments by two cellulose membranes. After evacuating the three partitions, the end spaces are filled with water vapour of different but constant pressures. The pressure in the intermediate chamber then adjusts itself so that the pressure differences across the membranes are inversely proportional to the diffusion constants. It was found that this pressure was always much nearer to that of the high vapour pressure side, independent of the direction of the diffusive flow. If one side was completely evacuated, the pressure in the middle chamber rose until it was equal to that of the high-pressure side, thus leading to the paradox, mentioned by King, that the amount diffusing may decrease with increasing concentration gradient.

These results can be explained most simply by taking into account two or more states of adsorption of the diffusing vapour in the adsorbing material, in which states the adsorbed molecules have markedly different mobilities. Then Fick's law applies, not to the adsorbed total, but only to the concentration of the mobile part (for keratin, Speakman's "capillary water"[3], and for cellulose Peirce's loosely bound "β-water"[4]) which reach appreciable values only at the higher concentrations of total water. A fuller account of the quantitative relationship between adsorption and the diffusion constant in the case of hair will be given elsewhere[5].

There is some evidence that similar phenomena can occur in the diffusion of adsorbed substances even where no swelling takes place (for example, in the diffusion of dyestuffs through cellulose[6]), though these conditions are complicated by the presence of ions. Here, too, the diffusion 'constant', as in the case of water diffusion, rises with the total concentration of the adsorbed material.

## Plant Nutrients in the Sea

Two difficulties have been raised by critics of the suggestion that, for the benefit of the fisheries, large-scale addition of plant nutrients to selected parts of the sea may be considered in the future[1]. The first difficulty concerns the quantities of nutrients required; Michael Graham describes these as "mountainous, nay astronomical"[2], and Dr. W. R. G. Atkins, on surer grounds, estimates the annual turnover of phosphorus in the phytoplankton of the English Channel at about one ton for each square kilometre of surface[3]. The quantity is neither astronomical nor even discouraging.

The Agricultural Statistics for 1937, the latest available, show that the quantity of phosphatic nutrients used in the United Kingdom and Eire in that year represented 201,000 tons as $P_2O_5$, equivalent to 2,718 lb. $P_2O_5$ or 1,187 lb. of phosphorus on each square kilometre of all crop and pasture land (41 million acres). But most fertilizers are applied to arable land (13½ million acres), so that the quantity of phosphorus distributed annually on an arable square kilometre is probably more than 3,000 lb. This is considerably in excess of the annual turnover in a square kilometre column of the English Channel. Dutch farmers use about six times as much fertilizer per acre as we do, so that compared with their liberal broadcasting on the surface soil, the turnover in the equivalent column of the English Channel seems almost puny.

The truth is that neither quantity nor cost of fertilizers matters very much to the farmer, provided a profitable return is produced. The return, and not the "mountainous" quantities or "vast expenditure", should be the criterion also in the sea. Furthermore, I conceive that if plant nutrient experiments are ever made in the North Sea, they will at first be limited in extent and confined to areas where currents, plankton and bottom fauna suggest possibilities of success. It seems more reasonable to develop a mediocre into a rich feeding ground with a minimum of labour than to transplant fish from one to the other.

The second suggested difficulty is that the soluble fertilizers once added to the surface waters will be "dissipated into the ocean"[3]. But the indications are that, in suitable areas, the fertilizers are almost immediately converted into phytoplankton, which is rapidly converted into zooplankton and bottom fauna, and no one suggests that the plankton or bottom fauna are dissipated into the ocean. The waters of the sea and their contents are more stable than might be supposed. There will be some loss, but there is considerable loss of fertilizers even on arable land, owing to rainfall and chemical action—the test again must be, are sufficient quantities utilized to make a profitable return? That has still to be decided.

## Professional Service in Universities, Technical Colleges and Industry

READERS of the leading article on "Professional Institutions" in *Nature* of December 9 may be interested to know that my Council had in fact taken the initiative in the way suggested in its opening paragraph. The views of the vice-chancellors of the universities and the principals of technical colleges of Great Britain are being sought as to:

(i) The conditions under which scientific workers of different grades in universities and technical colleges should undertake research or consulting work for industry, Government and Government-subsidized organizations.

(ii) The provisions that could usefully be made for the ready interchange of scientific workers between teaching posts, industry and Government service.

The nature of the replies will determine in what way we shall pursue the matter further.

ROBERT H. PICKARD.
(Chairman.)

Joint Council of Professional Scientists,
c/o The Institute of Physics,

# RESEARCH ITEMS

### Logarithmic Series and the Index of Diversity as Applied to Ecological Problems

IN a recent paper in the *Journal of Animal Ecology* (**32**, May 1944), Dr. C. B. Williams of the Rothamsted Experimental Station discusses this subject. He describes the application of a logarithmic series to a number of problems. It is found to fit extremely well to a large number of frequency series whether they be taken from insects, birds or plants. It also fits well to the number of genera with different numbers of species in standard classifications of groups of both animals and plants. The idea of the index of diversity is applied to problems of the number of species of plants on different areas and to the comparison of floras of different areas with interesting results. The author gives a classification of the 171 families of dicotyledons according to their index of diversity. It is hoped in this way to stimulate discussion of the factors which control differences and resemblances in this index. As a general rule it is found that those families with numerous species and genera have a large index of diversity, but yet there may be a very wide range of index in families of about equal size. This paper is one of considerable interest and deals in the main with problems of species, area and numbers of individuals and with the grouping of species into genera, many examples of both being quoted.

### New Zealand Turridæ

THE Turridæ is the largest family of gasteropod molluscs, and not only does it contain numerous living members, but it also has a large number of fossil representatives extending back with certainty to the Cretaceous if not earlier. In view of its extent and mixture of living and fossil forms it is not surprising that it presents a number of problems. 398 species of New Zealand Turridæ are described and figured in a well-produced memoir by A. W. B. Powell (*Bull. Auckland Inst. and Mus.* No. 2; 1942); 31 genera and subgenera and 144 species are new. The author takes advantage of this large amount of material to treat of several matters of general importance in the family, and includes a section on nomenclature in which he has endeavoured to give a synonymy of the generic names. The 362 names that have been employed are reduced to 284, which he considers are satisfactory both from the points of view of nomenclature and taxonomy. The second of the major general problems is the classification of the group with keys to the sub-families and genera. In this respect it is interesting to notice that classification according to the type of radula cannot be correlated with that based on shell features, but as too few of the radulæ are known it is not desirable to draw useful conclusions from this.

### Fishes from the Panama Bight

John Treadwell Nicholls and Robert Cushman Murphy describe a most valuable collection of fishes based mainly on material from an expedition conducted by the junior author on behalf of the American Museum of Natural History, February–May 1941, using as a base of operations the Diesel schooner *Askoy* ("A Collection of Fishes from the Panama Bight, Pacific Ocean", *Bull. Amer. Mus. Nat. Hist.*, **83**; 1944). The Panama Bight is defined as the part of the Pacific bounded by the concavity of the American coast between the Gulf of Panama and Point Santa Elene, Ecuador, and extending offshore towards the west and south. The pelagic collection at Station 49 (between the Colombian Coast and Malpelo Island) is of special interest. Here was encountered the upwelling of deep water, and the ocean was troubled by vertical waves in completely calm weather, resulting in large surface hauls of deep-water animals. The bulk of the material from this collection, however, was from coral brought up chiefly by the diving operations of Dr. John C. Armstrong, second in command of the expedition. The value of this paper is much augmented by the biological notes taken on the spot from the live specimens. These include descriptions of behaviour and coloration, not only of the captured fishes but also of those observed in their natural surroundings in the sea, such as the 'leaping mantas' which make somersaults in the air, and large sharks.

### Inheritance of Resistance in Melons

S. S. IVANOFF (*J. Hered.*, **35**; 1944) describes the methods and results obtained in raising melons suitable for market which are resistant to downy mildew and aphid attacks. Resistance behaves as a partial dominant during segregation. For example, the number of aphids on susceptible leaves was 433, on $F_1$ leaves 62, and on resistant leaves 4. Similarly, the number of lesions due to the fungus showed incomplete dominance. There would appear to be some connexion between resistance to aphid attack and resistance to the fungal attack, but the mechanism whereby resistance is achieved is unknown. The present resistant characteristics were derived from West Indian varieties of melons. When the original selections from the $F_1$s' were made, powdery mildew was not prevalent, so the new strains do not possess resistance to powdery mildew; but new selections are being made to obtain varieties resistant to all three troubles.

### Changes in X-Ray Sensitivity in Different Stages of Meiosis

A. H. SPARROW (*Proc. U.S. Nat. Acad. Sci.*, **30**, 147; 1944) has irradiated the different stages of meiosis from leptotene to the end of anaphase I in *Trillium erectum* and has compared the number of aberrations at each stage. He finds that if the sensitivity at leptotene-zygotene is 1·0, early pachytene is 2·3, pachytene 1·7, late pachytene 2·6, metaphase 1, 5·9, anaphase 1, 8·7, and microspore resting nucleus between 1 and 1·7. He suggests that the high concentration of desoxyribose nucleotides found at metaphase and the sensitivity to X-ray dosage are correlated. It is concluded that X-ray hits do not induce immediate breaks but potential breaks, which are not actually realized until the following division. The relationships of tumour and radiosensitivity to nucleic acid content are discussed.

### Hot Water Injury of Narcissus Bulbs

THE practice of treating narcissus bulbs with hot water at 110° F. for three hours is now a standard control for internal pests. Occasional subsequent damage to the flowers has been reported, however, and J. Wood (*J. Roy. Hort. Soc.*, 69, Pt. 10; Oct. 1944) has investigated the difficulty. Splitting of the corolla can be minimized by storage at 80° F. instead of 60° F. after lifting and before treatment

with hot water. Early lifted bulbs are also more susceptible to trumpet splitting, whereas late lifting may bring damage to the roots. Storage after treatment should be at a cool temperature of 48° F.

### Limiting Flow of Gas through a Nozzle

As previously mentioned in *Nature* (154, 90; 1944), J. R. Green and R. V. Southwell investigated the two-dimensional flow of a compressible fluid through a nozzle by Southwell's general 'relaxation' method. This method failed when the velocity was *supersonic*, that is, exceeded the local velocity of sound in the fluid. To deal with the supersonic case an iterative method, not depending on 'relaxation', was suggested. This has now been worked out in detail by L. Fox and R. V. Southwell (*Proc. Roy. Soc.*, A, 183, 38; 1944) for irrotational flow with steadily decreasing pressure and density. It is recalled that Osborne Reynolds's early (1886) approximate treatment of the nozzle problem found that the velocity of discharge could never exceed a certain limit, which was attained when the velocity in the narrowest section or 'throat' was equal to the local velocity of sound. He also concluded that there were two and only two possibilities after the gas had left the throat. Either its density and pressure steadily increased as it passed to the exit, or they steadily decreased. One of these two states, it was conjectured, was unstable. No intermediate state was possible. The more exact treatment of the present paper shows that there are *two* slightly different limiting values of the velocity of discharge. One of these is attained when the velocity both before and after the throat is subsonic, though, curiously enough, the velocity has supersonic values at two small regions near the wall at the throat. The other limiting value is for the case when the velocity is supersonic at the part of the nozzle between the throat and the exit. The second value is very slightly greater than the first, by 0·045 per cent. Osborne Reynolds's estimate of the first needs a small increase of 0·083 per cent. The convergence of the iterative process appears to show that the irrotational flow is stable from low velocities up to the lower limit, which gives great stability. On the other hand, the unique supersonic state appears to be unstable, though it may exist. The discussion of the physical interpretation of the work is reserved for a later paper.

### Hydrogen Bonds in Ethyleneimine

ALTHOUGH the existence of N—H—N bonds in nitrogen compounds has often been discussed, the compounds have been relatively complicated, such as pyrazoles, indazoles, amidines, etc. W. H. Thompson and G. P. Harris (*J. Chem. Soc.*, 301; 1944) have found good evidence of hydrogen bonding in the simple compound ethyleneimine. The infra-red absorption band at 3 $\mu$ due to the NH-group in this is appreciably displaced in wave-length on passing from the vapour to liquid, whereas other bonds are not much affected. Solutions in carbon tetrachloride, examined with wave-lengths between 2·9 $\mu$ and 3·5 $\mu$, showed the sharp band at 3·01 $\mu$ in dilute solution giving way at higher concentrations to a broader and more intense band with a maximum at about 3·1 $\mu$. The effect is precisely similar to the 'association' band found with hydroxylic substances, and points to association through N—H—N bonds. This is supported by boiling point relations.

### The Faintest Star

THE March issue of *Sky and Telescope* contains an account of van Biesbroeck's discovery of a faint companion to the star BD+4·4048°; Science Service has also described the discovery. Van Biesbroeck was comparing two plates taken at the prime focus of the 82-in. McDonald Observatory reflecting telescope when he discovered the companion of magnitude 18 at a separation of 74″ from the brighter star of magnitude 9·5. This separation corresponds to a distance of about 440 astronomical units, the distance of the system being nearly 20 light-years. The absolute magnitude of this star is 19 as compared with 5 for our sun, and about a million of these faint stars would be required to produce a combined brilliance equal to that of the sun. Owing to its great distance from the brighter star, it is almost certain that it shines, not by reflected light, but by its own light, and hence is a real star, not a planet. In the case of the invisible companion of 61 Cygni, the mass but not the luminosity were determined, and as its mass was about sixteen times that of Jupiter it was classified as a planet. If van Biesbroeck's new star has a mass comparable with that of the companion to 61 Cygni, it seems highly possible that the distinction between planet and star may cease to exist. Information which may be of assistance to astronomers is as follows: The position angle of the faint star is 150°; the common proper motion is 1·45″ towards position angle 204°, and the parallax is 0·17″.

### The Solar Eclipse of June 19, 1936

S. VSESSVIATSKY and E. Bougoslavsky, Kiev Astronomical Observatory, Sverdlovsk, U.S.S.R., deal with the coronal structure and the relationship observed between chromospheric and coronal phenomena during this eclipse (*Mon. Not. Roy. Astro. Soc.*, 104, 3; 1944). Four standard chronographs were located in the path of the eclipse at Beloretchenskaya, Ural, Omsk and Kuibyshevka, and thirty excellent plates of the corona and chromosphere were obtained. A number of important conclusions were deduced as a result of the work, but these cannot be dealt with in full. A very brief outline of them is as follows: Phenomena in the chromosphere and in higher-lying coronal regions are due to foci or centres of excitation on the sun's surface. Their frequency as well as their peculiarities of distribution are related to the heliographic latitude and they change with phases of the sun's activity. The coronal arch systems and the fan forms involved occasionally take on a helmet-shaped summit. This changes into thin rays distributed over the centres of excitation, these rays being connected by dark fibrous formations or dark flocculations. In the chromosphere, excitation gives rise to prominences which are 'imprisoned' in the interior of the coronal arch systems. The fan-shaped forms which characterize the structure of the corona over excited areas of the sun's surface have a discrete structure and represent a system of successive arches. From the presence of the helmet-shaped summits observed on many of the fans it is inferred that there are vertical fields in different regions of the corona at distances of ½ to 2 solar radii. The influence of the general field of the sun is reflected in the peculiarity of the inclination of the axes of the fans to the normal and also by the change in their inclination in relation to the phase of solar activity. This influence is also shown by the existence of a weakened luminosity inside the corona in a narrow equatorial belt of width about 7°.

# THE WILLOW TREE (*Salix* sp.)

By ALEXANDER L. HOWARD

"There is a willow grows aslant a brook
That shows his hoar leaves in the glassy stream".
SHAKESPEARE.

AMONG the many trees which adorn the countryside of Britain, this tree is one of the best known, and especially to those whose lives have been spent from earliest childhood in the country. A great many people have earned their livelihood in one way and another from its products, but those who have interested themselves in conserving or replenishing the stock are far too few, and almost entirely confined their attention to the bat willow, although perhaps with the exception of the ash tree the willow is one of those which will repay the planter within the least number of years. The fisherman, the basket-maker, and the gipsy are very intimate with the particular species which they know about, the first-named because of his continued controversy with the overhanging branches which interfere with his sport, but the latter since it has contributed to their livelihood.

It is unnecessary to describe the leaf or appearance of the tree, as it is so well known. Indeed, the narrow-pointed leaf, unlike most of our broad-leaved trees, is so prominent that its name has been borrowed for the description of other trees, such as the willow oak (*Quercus phyllus*), etc.

Everyone must be quite familiar with what we know as 'the willow pattern' of Chinese and Japanese origin in pictures and china ware; and also with the blue willow pattern of our own china, and more lately when a great designer made use of this attractive medium by the introduction of it into wall-papers. The Morris willow pattern also has become a well-known and admired addition to our domestic art. Whether the original Chinese, etc., pictured the willow as we know it is in some doubt. It has been suggested that perhaps the tree *Koelreuteria*, also a native of China, inspired the original willow pattern. While it would be interesting to decide the point, the beauty and likeness of both these trees is the principal subject of our interest.

The willow tree is regarded by different people with strangely opposite views: some think it a dull tree and take little interest in it, while others are delighted with the graceful form of the foliage and leaves, and its association with the banks of streams and rivers. The silvery blue presented by the leaves of many trees waving in the breeze adds greatly to the beauty of the landscape in those parts of the country frequented by the heron, the snipe and the duck. By the banks of streams, and in osier beds and the like, the willow figures more as a bush than a tree, and here it serves the purpose which it shares with the alder, of consolidating the banks, preventing erosion.

If care, and the study and practice of scientific measures are adopted, the tree will yield a very satisfactory financial result to the grower; but to succeed, diligence and study are required.

General knowledge is limited to two or three kinds, but Elwes mentions more than a hundred and sixty species, and Loudon more than two hundred. Many of these have been introduced from other countries.

The male and female trees of the original indigenous kinds have become the progenators of numbers of hybrids. I shall limit my remarks to seven kinds which are the better known and most prominent, namely: white willow, cricket bat willow, goat willow, bay willow, crack willow, golden willow, and the weeping willow.

## White Willow (*Salix alba*)

In single form this tree will attain a height of more than 100 ft., with a girth of 25 ft. 6 in., but generally speaking large-sized trees are not common. The white willow (*S. alba*) with its close relative *S. alba coerulea* are by far the most important, as these two yield the best wood for the making of cricket bats. *Salix alba* may easily be recognized by 'witches brooms'—a formation caused by a mite (*Eriophes salicis*).

Elwes mentions:

"a tree at Bury St. Edmunds, figured by Strutt . . . as the Abbot's willow, is one of the largest white willow of which we have record. It was measured . . . in 1822, when it was 72 ft. high by 18½ ft. in girth, and was estimated to contain 440 ft. of timber".

Inquiries at Bury St. Edmunds to-day (1944) fail to reveal any information about this tree, and for many years it has been inquired for with no better results.

## Cricket Bat Willow (*S. alba coerulea*)

This is a tree the origin of which would seem to be obscure, but it has been known in Great Britain since the beginning of the nineteenth century. It will attain a height of perhaps 100 ft. Of this Elwes says:

"Many trees of remarkable size, but comparatively young, have been felled for conversion into cricket bats. One of the largest was a tree at Boreham, Essex, which was planted in 1835, and felled in 1888, when it was 101 ft. high and 5 ft. 9 ins. in diameter. It weighed upwards of 11 tons, and was perfectly sound. It was felled by B. Warsop & Sons, who made from it no less than 1,179 bats".

Elwes was not often mistaken; but it would seem doubtful if any tree could make such growth in fifty-three years, as would equal more than one inch for every year.

He also says:

"Mr. Stuart Surridge purchased for £25, in 1910, a tree near St. Albans, which was about 80 ft. high and measured 5 ft. in diameter at 3 ft. from the ground. Judging from a photograph, it had a clean stem of about 16 ft. He states that the largest tree known to him grew at Robertsbridge, in Sussex, and measured 21 ft. in girth. This was felled in 1902, and produced over 1,000 cricket bats".

Mr. D. N. Bridger informs me that one of his workmen well remembers this tree being cut down and cleft. Mr. Bridger says that all the trees of *S. alba coerulea* are female, and he also says that many trees of *S. alba* have provided as good timber for cricket bats as *S. coerulea*. Elwes says, however, that the wood of *S. alba* is used for making cricket bats of an inferior kind. I also recall an occasion when an indignant purchaser of what he thought would prove to be cricket bat quality was informed that he had purchased the product of *S. alba* when he should have purchased *S. alba coerulea*. After exhaustive study I think the best results could be expected from the last-named, but it is quite possible that in the last thirty to forty years the character of the trees which have reached maturity may have altered.

The cricket bat manufacturer has become expert in his selection of the trees, but the same knowledge is not general among those who would find it to their advantage to become planters. Mr. Bridger emphasizes the importance of an abundant provision for the future of the cricket-bat making industry, his estimate of the annual output being in the neighbourhood of 250,000 bats per annum, men's size alone, while others name an even higher figure.

In 1915, it was discovered that in tropical countries, where the white ant has become a major pest, artificial limbs became a prey to these insects, and Prof. Groom and I were asked to find a wood which was immune to this attack. Exhaustive inquiry failed to discover anything except the willow suitable for the purpose, and in reply to an inquiry this year (1944) at the hospital at Roehampton, Mr. A. W. Shaw confirms the opinion, and says:

"willow is still the wood used in relation to wooden artificial legs, and no other wood has yet been found suitable. For metal artificial legs the foot is of willow".

The wood is pinkish-white, with a tough but softish grain, and besides the before-mentioned uses, provides the best-known timber for trug baskets, fruit baskets, linings for carts, barrows, and brakes for railway and other wagons, being especially good for the last-named, as it does not fire so readily as other woods from the friction of the wheels.

### Goat Willow (*Salix caprea*)

This tree is naturally regenerated by seed, but can be propagated by cuttings and by sets. Its principal value is for prevention of erosion, and it is used for making fences and sheep hurdles, for trug baskets and for handles of rakes.

### Bay Willow (*Salix pentandra*)

This is more noticeable for its attractive foliage than for its uses; it is distinguishable by its broad shining leaves.

### Crack Willow (*Salix fragilis*)

This is sometimes called 'open-bark' willow. The wood is of little importance, but the Rev. C. A. Johns tells us that "the roots afford a purple-red dye, and are still used in Sweden and in France to colour Easter Eggs".

### Golden Willow (*Salix vitellina*)

This tree is familiar to most people, and can be found in many gardens, parks and pleasure grounds. Fortunately, the nurseryman has found it sufficiently attractive to warrant production in large numbers, so that of late years householders have been able to gratify their inclination to make their gardens ornamental, and in this manner the tree has been justly introduced on a scientific scale. Elwes says:

"we have seen no trees of great size, the finest being probably two trees at Glasnevin, which are about 65 ft. in height and 8 ft. in girth".

The tree should be encouraged for its unusual grace and beauty.

### Weeping Willow (*S. babylonica*)

There must be very few who have not enjoyed the beauty of the weeping willow, a tree much more commonly seen half a century ago than to-day, and one which, if the plans for re-afforestation for the future are limited alone to the economic aspect, may insensibly vanish from our landscape.

It would appear that the first tree introduced to Great Britain was planted at Twickenham, and became famous, for Johns tells us:

"the first tree was planted at Twickenham, either by Mr. Vernon, a merchant of Aleppo, or by Pope. This was a favourite tree with the poet, and after his death became the object of so much curiosity that the possessor of his villa cut it down, to avoid being annoyed by persons who came to see it".

He also says:

"Loudon informs us that this tree was introduced into St. Helena from Britain by General Beaton, 1810. It was planted among other trees on the side of a valley near a spring; and having attracted the notice of Napoleon, he had a seat placed under it, and used to go and sit there very frequently, and have water brought to him from the adjoining fountain. About the time of Napoleon's death, in 1821, a storm shattered the willow in pieces, and after the interment of the Emperor, Madame Bertrand planted several cuttings from it on the outside of the railing which surrounded the grave. As none of these flourished, they were renewed in 1828; and from one of them, which outstripped the rest, were brought most of the cuttings which have been reared in various parts of the country. The oldest now in existence in Europe derived from this stock stands in the garden of the Roebuck Tavern on Richmond Hill".

And again:

"So popular has the weeping willow become as an ornamental tree, that it is said to be commoner in almost every country than in its native habitat, the banks of the Euphrates".

We are accustomed to the introduction of fashions in many directions, but it is curious that this should apply to the planting of particular trees. Sometimes the fashion has been to plant oak, another time acacia, and further instances might be quoted. Following the reign of terror and the Napoleonic era, certainly a wave of fashion spread over Europe, including Great Britain, for the planting of weeping willows, so that almost all the gardens and parks which date from this period included it among their ornamental trees.

Elwes gives some interesting information relating to this tree, and says:

"this was the name given by Linnaeus to the common weeping willow cultivated in Europe, which he erroneously supposed to have been identical with the trees growing by the rivers of Babylon, which are mentioned in Psalm cxxxvii, 1, 2.

"By the rivers of Babylon,  
There we sat down, yea, we wept,  
When we remembered Zion.

Upon the willows in the midst thereof  
We hanged up our harps.

"The latter are, without doubt, a species of Poplar (*Populus euphratica*). . . . The best that I have seen is perhaps a tree on the Promenade, Cheltenham, which was planted about 1860, and is still thriving, although its limbs have been supported by iron rods for some years. It measured in 1911 about 75 ft. by 9 ft. and on 24th November, 1911, after a severe frost, it still retained most of its leaves.

"There are several picturesque trees, but of no great height, growing on the banks of the Cam, behind the Colleges of Cambridge. These are exceeded in size by one

in the Fellows' Garden of King's College, which was about 45 ft. high and 10 ft. in girth in 1912, with the trunk decayed and mended with cement".

The weeping willow is surprisingly distributed. In addition to the numberless places in Asia and Europe where it thrives, Elwes informs us that "it attains much greater size and beauty in warm countries than it does in England" and that he had "seen none finer than in Chile".

# THERMODYNAMICS OF SORPTION ISOTHERMS: THE HYSTERESIS LOOP IN CAPILLARY CONDENSATION

By Dr. D. H. BANGHAM
British Coal Utilisation Research Association

IN any two-component system if $m_A$, $m_B$ are the masses of the components $A$ and $B$ and $g_A$, $g_B$ their respective Gibbs free energies *per gram*, then so long as there is equilibrium,

$$SdT - VdP + m_A dg_A + m_B dg_B = 0, \quad . \quad . \quad . \quad (1)$$

where $S$ is the entropy and $V$ the volume of the 'complex' of $A$ and $B$ whatever form it may take. If the 'complex' contains only condensed phases and the pressure is kept substantially constant (say, below 1 atmosphere) we can disregard the second term, and write for isothermal equilibrium:

$$m_A dg_A + m_B dg_B = 0 \quad . \quad . \quad . \quad . \quad (2)$$

An advantage of (2) over the more usual form of equation in terms of molecular quantities is that it is immediately applicable in cases where the molecular weight of one of the components (say, $A$) is large or unknown; it is particularly helpful, therefore, in examining the sorption relations of gels, the interaction between solid polymer and 'plasticizer', and such cases. Supposing $B$ to be a volatile liquid of molecular weight $M$, and that the 'complex' is at equilibrium with the vapour of $B$ at a pressure $p$, $f$ being the corresponding fugacity, we have, on substituting $RT/M \, d\log_e f$ for $dg_B$,

$$m_A dg_A + \frac{m_B RT}{M} \, d\log_e f = 0$$

$$g_A{}^0 - g_A = -\frac{RT}{M} \int_0^p \frac{m_B}{m_A} \, d\log_e f \quad . \quad . \quad . \quad (3)$$

where $g_A{}^0$ is the (Gibbs) free energy of *pure A*. The right-hand member of this equation can be evaluated experimentally.

The only conditions attached to the validity of (3) are that the structure and composition of $A$ should be statistically uniform (so that $m_B/m_A$ has a definite meaning) and that the same equilibrium should be attained by approach from either side. Primarily, we do not need to ask ourselves whether or not a true chemical compound is formed, whether the 'complex' is to be regarded as a one- or as a two-phase system, whether $B$ is or is not molecularly dispersed (to give a true solution), or whether, supposing surface interactions are involved, these are taking place at plane or at curved surfaces. In fact, however, a large number of cases have come to light where the relation between $(g_A{}^0 - g_A)$ and $m_B/m_B M$ corresponds to well-recognized two-dimensional equations of state or to a sequence thereof[1,2,3]. Where this occurs it appears justifiable, *prima facie*, to infer that: (1) $B$ is adsorbed as a film at the surface of $A$; (2) $A$ is characterized by possession of a definite surface area ($\Sigma$) per unit weight; and (3) that $(g_A{}^0 - g_A)$ stands for a decrement of *surface* energy and can be equated to $\Sigma(\gamma_0 - \gamma)$, where $\gamma_0$ is the surface energy of $A$ *in vacuo* and $\gamma$ its value in contact with the vapour of $B$ at $p$. It is convenient to assign the symbol $\Pi$ to $(\gamma_0 - \gamma)$ and regard $\Pi$ as a two-dimensional 'film pressure'; thus

$$\Pi\Sigma = (\gamma_0 - \gamma)\Sigma = \frac{RT}{M} \int_0^p \frac{m_B}{m_A} \, d\log f \, . \quad . \quad . \quad . \quad (4)$$

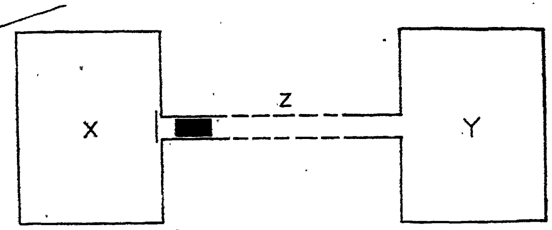
Now the sorption relations of many gels are such as to suggest the *filling-up* of capillary spaces, the quantities of different adsorbates at saturation representing roughly equal volumes of the different liquids[4]. According to the well-known capillary condensation hypothesis, the quantities sorbed at pressures below saturation are determined by the distribution of pore radii (the pores usually being considered cylindrical), the surface tensions $\gamma_B$ of the liquids, and the equilibrium angles of contact $\theta$, the relation between these parameters being the Kelvin equation:

$$p/p_0 = \exp.(-2V_m \gamma_B \cos\theta / rRT), \quad . \quad . \quad . \quad (5)$$

where $p_0$ is the saturation pressure of the liquid and $V$ its molecular volume. A necessary condition for capillary condensation is that $\theta < 90°$. Several authors have attempted to derive 'structure curves' for pore-size distributions from their sorption data on the basis of equation (5), $\theta$ generally being taken as zero. A weak point about this procedure is that, apart from its ability to become wetted by the component $B$, the only adjunct of A that is allowed to have a determining influence is the single property of *curvature*: $p$ should thus be uniquely determined by $r$.

By the use of equation (4), on the other hand, Gregg[2] has brought to light instances hitherto universally accepted as examples of capillary condensation, but in which the relations between $\Pi$ and the surface concentration reproduce in detail those of certain insoluble films on water. As the concentration rises, first a 'vapour', then an 'intermediate' and finally a 'liquid expanded' (or 'liquid condensed') film is formed. Thus, at the hands of different workers, the same sorption data may receive mutually incompatible interpretations in terms of film-forming characteristics on one hand and of pore structure on the other. The issue is complicated by the appearance of a hysteresis loop in some of the experimental adsorption isotherms referred to[5]; for over the range of the hysteresis the basic requirement of equations (1)–(4), namely, that the equilibria should be independent of the direction of approach, is no longer satisfied. For this reason we shall resort to the more cumbrous method of argument based on work cycles in the discussion which follows of the tenets of the capillary condensation hypothesis.

We suppose two large enclosures $X$ and $Y$ containing the vapour $B$ at pressures $p$ and $(p - dp)$ respectively, the corresponding fugacities being $f$ and $(f - df)$. Connecting $X$ and $Y$ is a long length of capillary tubing $Z$ of suitable material and of such (uniform) diameter that according to (5) capillary



condensation will just take place at $p$. $Z$ has a shutter at the end nearer $X$. Fitting into $Z$ also is a light piston of such diameter that as it moves it leaves the adsorbed film undisturbed, and merely prevents the liquid from leaking past. The following cycle is carried out isothermally: (1) $Z$ is first exposed to the vapour in $Y$, so that the adsorption equilibrium is established at $(p - dp)$, the shutter at $X$ being closed. (2) The piston being in position at the end of $Z$ nearer $X$, the shutter between $X$ and $Z$ is opened. Capillary condensation thus takes place, the piston being driven back. If $\Sigma$ is the internal area of the tube (more strictly that of the adsorbed film) the maximum work obtainable from the system by the pressure on the piston is $\Sigma\gamma_B \cos\theta$. (3) $Z$ is shut off from $X$ and (after removing the piston) exposed to $Y$, permitting the vaporization of the capillary-condensed molecules. According to the capillarity hypothesis based on equation (5), this process is *spontaneous*, so that *no work need be done* on the system. (4) The appropriate number of molecules of $B$ is compressed from $(p - dp)$ to $p$ and transferred back to $Y$.

The cycle as outlined contravenes the second law of thermodynamics, as indeed must any cycle in which the isothermal transfer of molecules from $X$ to $Y$ is made to yield a finite amount of work. The infringement lies in the assumption (implicit in calculations based on the Kelvin equation (5) ) that the capillary-condensed liquid will evaporate spontaneously at $(p - dp)$.

The essential requirement for compliance with the second law is that, if the tube fills at $p$, the fluid filling the tube should be able, without evaporation, to reduce its free energy by $RT\ d\log f$. This necessarily implies that $\gamma\cos\theta$ is a function of $p$; for $V_m$ cannot vary unless $\gamma\cos\theta$ varies. It follows that if we attempt to empty the tube by isothermal evaporation alone (as opposed to pushing the liquid out simultaneously with a piston) we must reduce the pressure in $Y$ by a *finite* amount to $(p - \Delta p)$. In other words, there will be a *hysteresis* loop in the isotherm.

To sum up, it has been established that: (1) where capillary condensation occurs, $\gamma\cos\theta$ is variable and not constant; and (2) capillary condensation cannot occur without hysteresis, though the converse statement does not necessarily hold. It further suggests itself that a quantitative relation must exist between the area within the loop and the work $\Sigma\gamma\cos\theta$. This relation and the more general form of equation (4) required to cope with cases of hysteresis and capillary condensation will be discussed in a later communication.

## THE FAILURE OF PATULIN

IN an earlier issue (*Nature*, 152, 619; 1943), account of patulin was given, and the results of clinical trial of it for the treatment of the common cold, conducted by Surgeon Commander W. A. Hopkins, R.N., with the aid of Naval personnel, as described in *The Lancet* (ii, 625, Nov. 20, 1943), were outlined. In that trial 57 per cent of the patients recovered completely in 48 hours, while only 9·4 per cent of the controls recovered in this time. Commander Hopkins was, however, wisely cautious about the interpretation of these results and pointed out that the etiology of the common cold is not yet fully understood. Prof. H. Raistrick stated at the time that patulin would not be issued for general use until the results of large-scale trials had been obtained. *The Lancet* now publishes the results of two such trials, which fully justify the earlier caution about the effect of patulin on the common cold.

J. M. Stansfield, A. E. Francis and C. H. Stuart-Harris (*The Lancet*, 370, Sept. 16, 1944) report on their laboratory experiments with patulin and on two clinical trials with it for the treatment of colds in 100 soldiers of an army primary training wing. For the second of these trials the method of administration used was the same as that used by Hopkins. Briefly, their conclusions are that patulin is bacteriostatic against a wide range of both Gram-positive and Gram-negative organisms, although its bacteriostatic action is materially reduced by incubation in broth or by the addition of horse serum. The margin between concentrations which kill mice and those which are bacteriostatic *in vitro* is small. Two experiments with mice indicated that it failed to cure infections with *Bact. typhosum* or with influenza virus A. (Hopkins (*loc. cit.*) found that patulin did not appear to have influenced the course of influenza in five human patients.) Controlled clinical trials for the treatment of the human common cold showed no advantage from the use of patulin as compared with the use of control buffer solutions without patulin, and that patulin did not appear to be useful for the treatment of human conjunctivitis.

Another trial (*The Lancet*, 373, Sept. 16, 1944) was more extensive. It was conducted by the Patulin Trials Committee of the Medical Research Council, the chairman of which was Prof. H. P. Himsworth; the committee included Prof. Raistrick and Dr. C. H. Andrewes. For this trial 668 patients were treated and there were 680 controls, the subjects being personnel of the Post Office, the Ministry of Supply, Haileybury and Rugby Schools and various engineering and electrical firms. The conclusion of this Committee is that "In a large clinical trial of patulin in widely distributed areas of Great Britain and lasting from the beginning of December 1943 to the middle of April 1944 no evidence was found that patulin is effective in the treatment of the common cold".

Thus ends a manful and commendable attempt to control that bugbear of our lives, the cold in the head, the effects of which are so great that it is not surprising that uninstructed people rushed into print to claim for patulin more than it could perform. It should not be forgotten that those who produced it never exceeded the scientific scepticism which awaits proof before it commends, and even then avoids exaggerated claims. Meanwhile, much has been learnt from these trials. All those who have conducted them emphasize the difficulty of assessing the effect

...nt of a condition like the common cold, in ...here are no real objective signs by which ...patient's subjective feelings can be checked. All the investigators made provisions for this and endeavoured to eliminate the subjective element. The experience thus gained will be of great value when further remedies are presented for test.

...cussing these trials, *The Lancet* suggests that ...d results obtained by Hopkins may have been ... the effects of patulin on the particular organ... responsible for the colds which he treated, or ... in view of patulin's failure in the later Army Medical Research Council trials, its success in the Navy trials was one of those rare events which ... sometimes happen.

Whether patulin may yet have other uses, further work will doubtless show. G. LAPAGE.

## THE HEATHER BEETLE

THE British Field Sports Society has recently issued a booklet entitled "Report on the Biology and Control of the Heather Beetle". In view of the damage caused by this insect in the past, this report and its findings will be of very definite interest to those who are concerned with the management and preservation of moorlands. These include not only the moor owner and his shooting tenants, but also the sheep grazier and, to a lesser degree, the bee-keeper. The activities of this beetle deplete the numbers of grouse, impoverish the grazing and decrease the honey-flow. The report under notice is based upon investigations carried out between 1937 and 1940 under the direction and supervision of Dr. ...E. Cameron, of the Department of Agriculture and Forest Zoology, University of Edinburgh.

The beetle in question is *Lochmœa suturalis*, a member of the family Chrysomelidæ. Severe damage ... the heather is most prevalent in Scotland; it is ... troublesome in Germany and Holland. In July ... August, the leaves and stems of heather attacked ...he larvæ of the beetle become fox-red where ...y have been chewed and partially stripped of ...k and especially the ends of young shoots. The ...t severe damage is done to old heather of twenty ...s or more. Young heather is also attacked but permanent damage rarely happens. Attacks are most prevalent and the beetles most abundant over flat wet moorlands, but well-drained slopes are not often affected. The eggs of the beetle require humid conditions for their development and are chiefly laid on *Sphagnum* moss. Rainfall in spring and early summer during its breeding season is believed to determine its rate of multiplication. Seasons of very low precipitation seem, on the other hand, to check its activities. There is only one generation in the year. The beetles overwinter in the ground or among moss, etc., and begin to lay eggs in mid-April. Incubation lasts three to four weeks in Nature, and hatching of the larvæ begins early in June ...n they climb the plants in order to feed on ... young shoots and leaves. The adult beetles ...ear first in the latter half of August but do not become abundant until late in September. Ling heather, *Calluna vulgaris*, is the chief and perhaps the only food plant of this insect. The only natural enemy of any importance was found to be the ladybird *Coccinella hieroglyphida* which, however, did not appear to exert any significant degree of control of the beetle.

The problem of dealing with the insect is a question of moorland economics. Treatment of the heather with derris and pyrethrum dusts serves to check the larvæ. General adoption of this method over wide areas of moorland is out of the question owing to the costs of material and labour. Muir-burning in Scotland is not permissible at the time it would be most efficacious. There is no practice of moorland management that should be more encouraged than a ten-year rotational system of burning, since it induces young growth which recovers more quickly from beetle attack than does old heather. Dusting and burning, however, are of secondary importance to drainage. The elimination of excessive moisture by a proper system of surface drains is the only known means by which permanent control of the pest may be achieved.

This report, it may be added, can only be obtained direct from the British Field Sports Society, Petworth, Sussex, price 1s. post paid. It is well printed and, with thirteen full-page half-tone plates, is remarkably cheap.

## FORTHCOMING EVENTS

### Monday, January 1

ROYAL GEOGRAPHICAL SOCIETY (at Kensington Gore, South Kensington, London, S.W.7), at 2.30 p.m.—Mrs. Harold Ingrams: "Young People of the Hadhramaut" (with films) (Christmas Lecture for Young People).

### Tuesday, January 2

ROYAL INSTITUTION (at 21 Albemarle Street, London, W.1), at 2.30 p.m.—Sir Harold Spencer Jones, F.R.S.: "Astronomy in our Daily Life", 3: "How we get our Time" (Christmas Lectures).

INSTITUTION OF CIVIL ENGINEERS (WORKS CONSTRUCTION DIVISION) (at Great George Street, Westminster, London, S.W.1), at 5.30 p.m.—Lieut.-Colonel C. M. Norrie: "The Organization of Civil Engineering Work".

### Wednesday, January 3

ROYAL SOCIETY OF ARTS (at John Adam Street, Adelphi, London, W.C.2), at 1.45 p.m.—Lieut.-Commander Rupert T. Gould: "The Art of Measuring Time" (Dr. Mann Juvenile Lecture).

### Thursday, January 4

ROYAL INSTITUTION (at 21 Albemarle Street, London, W.1), at 2.30 p.m.—Sir Harold Spencer Jones, F.R.S.: "Astronomy in our Daily Life", 4: "Finding the Longitude" (Christmas Lectures).

### Friday, January 5

ROYAL GEOGRAPHICAL SOCIETY (at Kensington Gore, South Kensington, London, S.W.7), at 2.30 p.m.—Surgeon-Commander Bingham: "Sledging with Dog Teams in the Antarctic" (with films) (Christmas Lecture for Young People).

### Saturday, January 6

ROYAL INSTITUTION (at 21 Albemarle Street, London, W.1), at 2.30 p.m.—Sir Harold Spencer Jones, F.R.S.: "Astronomy in our Daily Life", 5: "Clocks and Time Keeping" (Christmas Lectures).

## APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

IRRIGATION ENGINEER, Soils Mechanics Laboratory, Irrigation Department, Ceylon—The Ministry of Labour and National Service, Central (T. and S.) Register, Room 5/17, Sardinia Street, Kingsway, London, W.C.2 (quoting Reference No. E.1258.A) (January 1).

INSPECTOR OF AGRICULTURE, Sudan Government—The Ministry of Labour and National Service, Central (T. and S.) Register, Room 5/17, Sardinia Street, Kingsway, London, W.C.2 (quoting Reference No. F.3285.XA) (January 2).

EXECUTIVE ENGINEER by the Government of Trinidad—The Ministry of Labour and National Service, Central (T. and S.) Register, Room 5/17, Sardinia Street, Kingsway, London, W.C.2 (quoting Reference No. E.1266.A) (January 3).

ANALYTICAL CHEMIST for manufacturers engaged on high priority work, S.E. London area—The Ministry of Labour and National Service, Central (T. and S.) Register, Room 5/17, Sardinia Street, Kingsway, London, W.C.2 (quoting Reference No. F.3292.XA) (January 4).

EXPERIENCED ENGINEERS, QUANTITY SURVEYORS and ARCHITECTS at the Building Research Station, Garston, Watford, for work in connexion with the preparation of codes of practice—The Ministry of

Labour and National Service, Central (T. and S.) Register, Room 5/17, Sardinia Street, Kingsway, London, W.C.2 (quoting Reference No. E.1084.A) (January 4).

ELECTRICAL ENGINEER (temporary staff) by the Nigerian Government Public Works Department—The Ministry of Labour and National Service, Central Register, Room 5/17, Sardinia Street, Kingsway, London, W.C.2 (quoting Reference No. D.926.A.) (January 9).

ASSISTANT LECTURESHIP IN MECHANICAL ENGINEERING, and an ASSISTANT LECTURESHIP IN ELECTRICAL ENGINEERING—The Registrar, College of Technology, Manchester 1 (January 12).

ENGINEER and MANAGER OF THE HARROGATE WATER UNDERTAKING—The Town Clerk, Municipal Offices, Harrogate (endorsed 'Water Engineer') (January 15).

ASSISTANT CYTOLOGIST to take part in routine and research investigations on Cancer—The Secretary, Royal Cancer Hospital (Free), Fulham Road, London, S.W.3 (February 1).

SENIOR CENTRIFUGAL PUMP DESIGNER for a firm in the South Midlands—The Ministry of Labour and National Service, Central (T. and S.) Register, Room 5/17, Sardinia Street, Kingsway, London, W.C.2 (quoting Reference No. C.2396.XA) (February 4).

## REPORTS and other PUBLICATIONS

*(not included in the monthly Books Supplement)*

### Great Britain and Ireland

Eighth Report from the Select Committee on National Expenditure, Session 1943–44. The Chemical Controls. Pp. 12. (London: H.M. Stationery Office.) 2*d.* net. [1611

Ministry of Education. Memorandum on the Draft Bu ng Regulations: Being the Draft dated November 3, 1944, of the Leg lations prescribing Standards for School Premises, 1944, proposed to be made under Section 10 of the Education Act, 1944. Pp. 24. (London: H.M. Stationery Office.) 6*d.* net. [1611

Evolution—Fact or Fable: or, Do We Really Come from an Ape-like Stock? By R. L. Wheeler. Pp. 42. (London: The Author, 111 Capel Road, E.7.) [1711

Recruitment to Established Posts in the Civil Service during the Reconstruction Period: Statement of Government Policy and Civil Service National Whitley Council Report. (Cmd. 6567.) Pp. 24. (London: H.M. Stationery Office.) 4*d.* net. [2311
